Fig. 1. Solvent: 2-butanone/glacial acetic acid/water/sodium *p*-tosylate v/v (40:40:10:1 g) layer, according to Wang (ref. 8) (Toyo Rayon Co., Amilan CM 1011 (26°)). Loading, 0.5 µg. Photographed by transmitted artificial light. Key: 1, New Cocaine; 2, amaranth; 3, Ponceau SX; 4, tartrazine; 5, orange I; 6, eosin (sodium-salt); 7, naphthol yellow S; 8, sunset yellow FCF; 9, Ponceau 2R; 10, Ponceau 3R.

solvent mixture is sufficient, and that an increase of the percentage of the salt present effects the increase of *R<sub>F</sub>* values observed. This throws open the possibility that compounds with a sulphonic acid group may be efficiently resolved by polyamide layer chromatography with the solvent mixture containing sodium *p*-toluenesulphonate because all the food colours which I have tested have a sulphonic acid group in the molecule except eosin. Eosin shows a circular spot without addition of sodium *p*-toluenesulphonate.

No.	Table 1				
	I	II	Solvents III	IV	V
(1) New Cocaine	0.12	0.03	0.26	0.13	0.12
(2) Amaranth	0.14	0.06	0.43	0.22	0.14
(3) Ponceau SX	0.25	0.16	0.48	0.35	0.16
(4) Tartrazine	0.25	0.13	0.55	0.36	0.26
(5) Orange I	0.40	0.41	0.59	0.49	0.42
(6) Eosin (Na-salt)	0.53	0.64	0.67	0.61	0.54
(7) Naphthol yellow S	0.36	0.44	0.70	0.58	0.35
(8) Sunset yellow FCF	0.46	0.28	0.68	0.49	0.43
(9) Ponceau 2R	0.48	0.30	0.70	0.52	0.45
(10) Ponceau 3R	0.48	0.31	0.70	0.53	0.47

Solvents I, 2-butanone/glacial acetic acid/water/sodium tosylate v/v (20:40:10:1 g); II, 2-butanone/glacial acetic acid/water/sodium tosylate v/v (40:40:10:1 g); III, acetone/glacial acetic acid/water/sodium tosylate v/v (40:40:10:1 g); IV, dioxane/glacial acetic acid/water/sodium tosylate v/v (40:40:10:1 g); V, *t*-butanol/glacial acetic acid/water/sodium tosylate v/v (20:10:5:1 g).

I found 10 cm development was sufficient because the spots were very small and sharp. The time required to ascend 10 cm from spot origin is 2.5–3 h except with the system containing *n*-butanol or *t*-butanol which required 6 h. The colours are very faint because of the small sample size (about 0.5 µg) and therefore they do not give good contrast on photographic paper; however, it is easy to locate the spots by transmitted daylight. Ponceau 2R and Ponceau 3R cannot be separated by these solvent systems probably because of their similarity in structures.

Polyamide layer is very durable and easy to handle. This layer with its sorption character is more suitable for analysing food colours than other adsorbents.

### Polyamide Layer Chromatography of Indoles

POLYAMIDE was found to adsorb various types of compounds by hydrogen bonding. Carelli *et al.* were the first to report that polyamide powder is an excellent adsorbent for column chromatography of phenols and lower fatty acids, for example, formic acid, acetic acid and propionic acid<sup>1</sup>. Later, Endres<sup>2</sup> found that nitro and sulphonic acid groups are also adsorbed by polyamide powder column. Wang has applied polyamide layer chromatography to several compounds<sup>3</sup> including the separation of lactones<sup>4</sup>.

Here we report the result of our experiment on indole derivatives. In the early stage of development of thin layer chromatography, Stahl<sup>5</sup> showed excellent separation of twenty simple indole derivatives by two dimensional chromatography on silica gel *G* thin layer. More recently, some Russian workers<sup>6</sup> investigated forty-seven basic

Fig. 1. Solvent system: chloroform/ethyl acetate/glacial acetic acid (7:2:1). Length of run: 10 cm, 1.5 h. Key: Polyamide layer according to Wang (ref. 7) 15 cm x 15 cm. Colour reagent: 1 per cent aqueous ferric chloride + 1 per cent aqueous potassium ferricyanide (v/v 1:1) (ref. 8). (1), 5-hydroxy indolyl-3-acetic acid; (2), tryptophan; (3), serotonin; (4), abrine (*N*-methyl tryptophan); (5), tryptamine; (6), indolyl-3-acetic acid; (7), *N*-methyl tryptamine; (8), melatonin (*N*-acetyl-5-methoxy tryptamine); (9), 5-hydroxy-tryptophan; (10), indole; (Mix.), mixture of above substances.

Fig. 2. Solvent system: chloroform/glacial acetic acid (9:1). Length of run: 10 cm, 1.5 h.

Fig. 3. Solvent system: 80 per cent formic acid/water (1:2). Length of run: 10 cm, 1.3 h.

Fig. 4. Solvent system: diethyl ether/glacial acetic acid (9:2). Length of run: 10 cm, 1.5 h.

neutral and acidic indole derivatives and established that the twenty-eight basic and neutral indoles can be separated by alumina thin layer chromatography, and indicated that it is necessary to use paper chromatography to separate the acidic indoles.

In our experiments, ten simple indoles were used and four solvent systems—(1) chloroform/ethyl acetate/glacial acetic acid (7:2:1), (2) chloroform/glacial acetic acid (9:2), (3) 80 per cent formic acid/water (1:2), and (4) diethyl ether/glacial acetic acid (9:2)—were found to be useful for separation (see Table 1 and Figs. 1–4). The system chloroform/ethyl acetate/glacial acetic acid gives especially good resolution of these substances on a 10 cm solvent run.

Indole travels fastest as a spot in solvents 1, 2 and 4, but slowest in solvent 3. The presence of functional groups which can be adsorbed by polyamide was found to affect the  $R_F$  values. Tryptamine tends to show heavy tailing in solvent systems 1 and 2, but not in solvent 3 or 4, while with *N*-methyl tryptamine there is no tailing in any of these solvent systems. It seems that a free amino group is responsible for the non-linear adsorption of tryptamine in solvent systems 1 and 2, because *N*-methyl tryptamine gives a circular spot regardless of the solvent systems used.

Table 1.  $R_F$  VALUES OF INDOLES ON POLYAMIDE LAYERS

Compound	Solvent			
	(1)	(2)	(3)	(4)

(10) Indole	0.83	0.85	0.21	0.93

Solvents as in text.

These experiments provide evidence of polyamide sorption of the indole skeleton. It is probable that acidic hydrogen of pyrrole nitrogen is the centre of adsorption. Investigations of other indole derivatives and the application of this technique to indole metabolites in human urine are in progress.

## SOIL SCIENCE

### New Method for measuring Heat Flux Density at the Surface of Soils or of Other Bodies

Two methods for determining thermal conductivity  $\lambda$ , and heat capacity per unit volume  $C$ , at a soil surface have recently been developed<sup>1</sup>. One method also measures the heat flux density.

A block of an appropriate material, at a uniform temperature, is placed on the soil surface and the temperature of the contact plane recorded. The product  $\lambda C$  and the heat flux density can be calculated. In experiments by myself and by Derksen, Schneider and Belghith, 'Perspex' blocks of  $10 \times 10 \times 4$  cm dimensions were used<sup>2</sup>. The temperature near the centre of the contact plane ( $10 \times 10$ ) was recorded for about 6 to 12 min.

The method might also be useful outside the field of soil science since it possesses the following favourable features: no correction need be made for the presence of the block; no sensing elements need be placed in the soil; a good thermal contact between block and soil surface is not essential.

The temperature near the centre of the contact plane is calculated from the theory of two semi-infinite bodies, each filling a half space, which are suddenly brought into contact along the plane  $z = 0$  at the instant  $t = 0$  (ref. 3). This happened during a certain interval of time in which the contact with the other body affects only a layer of a depth which is much smaller than the dimensions of the body. In the experiments referred to, this depth was about 1 to 2 cm.

If at  $t = 0$  the initial temperature in the block is uniform at  $\vartheta_1$  and in the upper soil layer is at  $\vartheta_2 + Ez$ , where  $z$  is the depth, the temperature in the plane of contact becomes

$$\vartheta(t) = \frac{\vartheta_1 \sqrt{\lambda_1 C_1} + \vartheta_2 \sqrt{\lambda_2 C_2}}{\sqrt{\lambda_1 C_1} + \sqrt{\lambda_2 C_2}} + \frac{2}{\sqrt{\pi}} \frac{E \lambda_2}{\sqrt{\lambda_1 C_1} + \sqrt{\lambda_2 C_2}} \sqrt{t} \quad (1)$$

The indices 1 and 2 refer to the block and the soil, respectively.  $-E \lambda_2$  is the initial heat flux density, since  $E$  is the gradient of the temperature in the soil near its surface. It can be calculated from the slope of the  $\vartheta(t)$  versus  $\sqrt{t}$  curve if  $\vartheta_1$ ,  $\vartheta_2$  and  $\lambda_1 C_1$  are known and  $\lambda_2 C_2$  is found from the temperature immediately after contact.

If two blocks are used at different initial temperatures, the initial surface temperature of the soil  $\vartheta_2$  need not be known, but can be calculated.

Equation (1) holds only for perfect thermal contact, that is,  $\vartheta_1(0, t) = \vartheta_2(0, t)$ , where  $\vartheta_i(0, t)$  denotes the limit of the temperature in body  $i$  for  $z$  approaching zero.

The records show that a more realistic assumption is  $\vartheta_1(0, t) = \vartheta_2(0, t) + \mu H(t)$ , in which  $H(t)$  is the heat flux density pointing from the block into the soil and  $\mu$  a positive constant which indicates the quality of the contact. With this assumption one obtains for the temperature at the contact face of the block

$$\vartheta_1(0, t) = \frac{\vartheta_1 \sqrt{\lambda_1 C_1} + \vartheta_2 \sqrt{\lambda_2 C_2}}{M} - \frac{NE \lambda_2}{M^2} + \left[ \frac{(\vartheta_1 - \vartheta_2) \sqrt{\lambda_2 C_2}}{M} + \frac{NE \lambda_2}{M^2} \right] e^{\frac{M^2}{N^2} t} \cdot \operatorname{erfc} \left( \frac{M}{N} \sqrt{t} \right) + \frac{2}{\sqrt{\pi}} \frac{E \lambda_2}{M} \sqrt{t} \quad (2)$$

$M = \sqrt{\lambda_1 C_1} + \sqrt{\lambda_2 C_2}$ ,  $N = \mu \sqrt{\lambda_1 C_1 \lambda_2 C_2}$ , and  $\operatorname{erfc}$  is the complement of the error function,  $\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$ .  $\lambda_2 C_2$ ,  $E \lambda_2$  and  $\mu$  can be calculated if  $\vartheta_1$ ,  $\vartheta_2$  and  $\lambda_1 C_1$  are known and the use of two blocks renders a separate determination of  $\vartheta_2$  superfluous. In our experiments the term with  $\operatorname{erfc} \left( \frac{M}{N} \sqrt{t} \right)$  became negligible after an interval ranging from 10 sec to 2.5 min in the individual experiments.

## AGRICULTURE

### Relation between Mineral Deficiency and Amine Synthesis in Barley

It has been shown that when potassium is deficient, barley—like other species—accumulates the amines putrescine and agmatine<sup>1,2</sup>, which are derived from arginine. The product of decarboxylation, agmatine, is converted to putrescine with the intermediate formation of *N*-carbamylputrescine. Furthermore, when phosphorus is deficient, barley has an increased agmatine content, but there is no corresponding increase in putrescine<sup>3</sup>. In the plants deficient in potassium the production of

agmatine and putrescine is accompanied by an increase in the activity of the enzymes, arginine carboxy-lyase and *N*-carbamylputrescine amidohydrolase<sup>4,5</sup>. It was of interest, therefore, to compare the activities of these two enzymes and the production of amines when phosphorus and potassium were deficient, and also to investigate the concentrations of agmatine and putrescine when some other essential elements were deficient.

Plants of a variety of barley resistant to mildew (H.B. 248-17-4) were grown in sand culture using the calcium type nutrient solution of Richards and Berner<sup>6</sup>. Those plants which were subjected to potassium deficiency received one-sixteenth of the potassium supply of the controls (-K), and those subjected to phosphorus deficiency received one-sixty-fourth of the optimum phosphorus supply (-P).

The plants, grown to the stage of the sixth leaf, in the open air, were sampled in duplicate on three occasions at weekly intervals, and the youngest fully expanded leaf from each tiller was analysed. In addition, other plants were grown on two occasions in water culture in which the concentration of calcium or magnesium had been reduced to one-tenth, or from which sulphur, iron or manganese had been omitted. In these treatments, the latest fully expanded leaves were sampled 2.5 weeks (first occasion) and 3.5 weeks (second occasion) after the start of the treatment.

Table 1. CONTENTS OF ENZYME AND AMINE AS INFLUENCED BY DEFICIENCY OF POTASSIUM OR PHOSPHORUS

Time of sampling	Treatment	Carboxy-lyase (μmoles/g fresh weight/h)	Amidohydrolase (μmole/g fresh weight/h)	Agmatine (μmole/g fresh weight)	Putrescine (μmole/g fresh weight)
1	Control	0.0004	0.32	0.10	Trace (<0.2)
	-P	0.033	0.27	0.32	Trace
	-K	0.134	0.24	1.02	2-8
2	Control	0.035	0.13	0.10	Trace
	-P	0.074	0.14	0.41	Trace
	-K	0.098	0.33	1.05	6-8
3	Control	0.027	0.09	0.13	Trace
	-P	0.058	0.12	0.51	Trace
	-K	0.115	0.23	1.11	6-8
	L.S.D. 5%	0.024	0.08	0.24	
	1%	0.035	0.12	0.32	

Putrescine and agmatine were extracted, purified on ion-exchange resins, and estimated by paper chromatography or colorimetry as described by Sinclair<sup>7</sup>. The activities of arginine carboxy-lyase and *N*-carbamylputrescine amidohydrolase were determined by the methods of Smith<sup>4,5</sup>.

Table 1 shows that significant increases in the activity of carboxy-lyase were induced by deficiencies of phosphorus or potassium. Amidohydrolase activity was increased by deficiency of potassium in two out of three samples, but remained unaffected by deficiency of phosphorus.

Concentrations of agmatine, increased by deficiencies of either phosphorus or potassium, seem to reflect the increases of carboxy-lyase activity involved in its production. Putrescine, the product of amidohydrolase activity, occurred in measurable amounts only in the leaves deficient in potassium.

In the plants raised in water culture, the concentration of agmatine was approximately trebled when calcium or sulphur were deficient; the concentration from magnesium or manganese was approximately doubled, while that of putrescine remained unchanged. Replicate samples of the plants deficient in calcium and sulphur, when analysed for their enzyme content, showed no change in the concentration of amidohydrolase, but did show an increase in that of carboxy-lyase in the samples deficient in calcium. These results suggest that the increased production of agmatine may be associated with deficiencies of several mineral nutrients, whereas further conversion of agmatine to putrescine through *N*-carbamylputrescine<sup>8</sup>

appears to be more specifically related to deficiency of potassium. The possible function of the accumulation of amines as a homeostatic mechanism for the maintenance of ionic balance, when potassium is deficient, has been discussed previously<sup>8,9</sup>.

## Pentobarbital Sodium Salt, a Systemic Agent for Control of Powdery Mildew of Cucumber

PHENOBARBITONE (phenobarbital) has been reported to control powdery mildew of marrow<sup>1</sup>. During 1963 and 1964 we have tested a series of barbituric acid derivatives on powdery mildew of cucumber caused by *Sphaerotheca fuliginea* (Schlecht. ex. Fr.) Poll.

Cucumber seedlings, cultivar "Lange gele tros", were grown in pots in the greenhouse until the cotyledons were well developed. These cotyledons were sprayed with suspensions of the chemicals in water with an added surface-active compound. They were then dusted with spores of the fungus by shaking over them cucumber plants heavily infected with powdery mildew. After an incubation period of 10-14 days in the greenhouse the results were assessed and recorded as percentages of the mildew on the cotyledons of unsprayed control plants.

The tests to assess systemic activity were performed in a room maintained at a climate of about 70 per cent relative humidity, and a temperature of 21° C during the 16 h of light (fluorescent light, 3,000-6,000 lux) and

Table 1. POWDERY MILDEW ON COTYLEDONS OF CUCUMBER SEEDLINGS

Sodium salt of	R	Dosage (p.p.m.)				
		Spray test		Systemic test		
		3,000	1,000	100	100	30 10 3
Pentobarbital		3	27	94	0	0 5 100
Amylobarbitol		96	100		13	70
Phenobarbital		26	66	100	0	0 9 70

Results are expressed as percentages of control plants.

18°C during the 8 h of darkness. The cucumber seedlings were grown in the greenhouse on a nutrient solution; 48 h before infection they were moved to fresh solutions to which the chemicals had been added and placed in the adjusted climate; 7–8 days after infection the solution which had been taken up was replaced; infection and assessment of the results 12–14 days later were performed in the same way as in the spray tests.

Our results generally agree with those reported by Zaracovitis: barbituric acid and a number of its derivatives did not show any activity, either after application on to the cotyledons or after addition to the nutrient solutions, whereas phenobarbital (luminal) and its sodium salt did protect the plants after application to the roots (complete control at 30 p.p.m.). Protection at about the same level was obtained by pentothobarbital sodium salt, but the best results were obtained with the sodium salt of pentobarbital (nembutal) which was active not only after root application but also after spraying (Table 1). A closely related compound, amylobarbitol sodium salt (amytal sodium), did not show any activity at all. In the systemic tests the three compounds caused symptoms of slight phytotoxicity: retardation of growth, yellowing of the leaves.

Zaracovitis<sup>1</sup> suggested that phenobarbitone and 6-azauracil could have a similar mode of action. Dekker obtained in a leaf disk test complete antagonism of 0.6 p.p.m. of 6-azauracil by 80 p.p.m. of uracil<sup>2</sup>. We performed a similar test with pentobarbital and phenobarbital. Uracil in a concentration of 500 p.p.m., however, failed to counteract the protective effect of 30 p.p.m. of these compounds.

Spraying with 3,000 p.p.m. of the compounds did not protect apple seedlings against powdery mildew after artificial infection with *Podosphaera leucotricha* (Ell. and Evenh.) Salm.

## APPLIED SCIENCE

### Electrochemical Time Switch

AN electrochemical time switch for a.c. current has been developed. It consists of a copper electrode, two tantalum electrodes with oxide films produced by heating<sup>1</sup> and an electrolytic solution (see Fig. 1). The tantalum plate is 99.9 per cent pure tantalum heated for about 12 sec in an electric oven (enclosed heating element) at 670°C in air to form the oxide film. For convenience, the copper electrode is referred to as the control electrode and the tantalum electrodes are referred to as the main electrodes.

Under the open circuit conditions shown in Fig. 1, there is no d.c. voltage at the control electrode. The path between the main electrodes has an extremely high resistance and there is no current through the load resistance, apart from a negligible small leakage current.

In Fig. 1, the control switch is closed with the result that the control electrode becomes positive with respect to the main electrodes. The current which flows in the

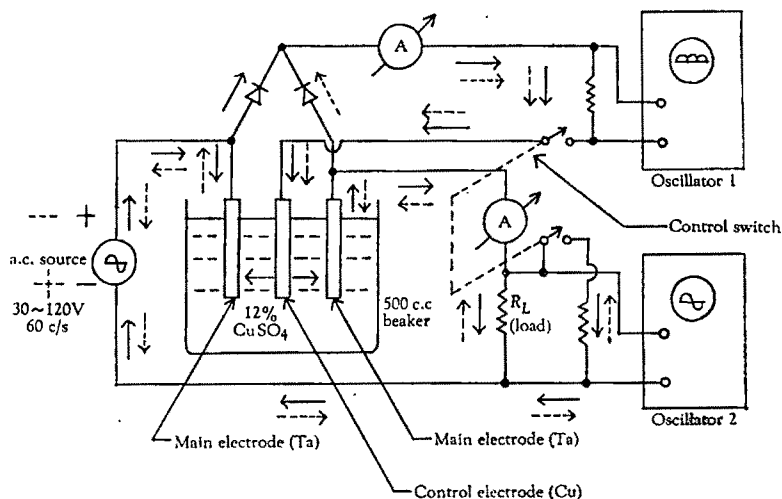

Fig. 1. Experimental apparatus.

circuit is shown by solid and dotted arrows in Fig. 1. Copper is deposited at the surfaces of the tantalum electrodes and the resistance between the main electrodes is decreased, so that the a.c. current through the load resistance is increased.

After the copper is deposited on the main electrodes, the current flows between them even when the control switch is open. The current between the main electrodes maintains its initial magnitude until the deposited copper is removed.

Fig. 2. Time switch characteristics. Temperature of electrolytic solution, 20°C. Time for which control switch keeps closed: ●, 1 sec; □, 2 sec; ×, 3 sec; △, 4 sec; ○, 5 sec.  $R_L$ , 100 V, 10 W lamp;  $R$ , 100 V, 100 W lamp; control current, 0.93 amp; a.c. source, 100 V.

The duration of the current between the main electrodes (main current) depends on the time for which the control switch is closed. Fig. 2 shows the relation between the duration of the main current and the time for which the control switch is closed. Fig. 2 also shows that this electrochemical device has the characteristics of a time switch. This type of time switch is extremely simple to produce in comparison with mechanical time switches.

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.20 p.m.—Dr. W. K. Taylor: "The Memory of a Learning Machine".\*

INSTITUTION OF CHEMICAL ENGINEERS, SOUTH EASTERN BRANCH (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Annual General Meeting. 5.30 p.m.—Paper by Mr. E. E. Charlton.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. A. E. Green: "Assessment of Sensing Channels for High-Integrity Protective Systems".

UNIVERSITY OF LONDON (at the Institute of Child Health, Gullford Street, London, W.C.1), at 5.30 p.m.—Dr. A. D. Bangham: "Lipid Structures and Cell Membranes". (Second of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

UNIVERSITY OF LONDON (at the Royal Free Hospital School of Medicine, 8 Hunter Street, London, W.C.1), at 5.30 p.m.—Prof. O. Eränkö (Helsinki): "Histochemical Aspects of Catecholamines and Cholinesterases".\*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, ELECTRO-Acoustics GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Symposium on "Radio Microphones". Speakers: Mr. M. L. Gayford, Mr. G. R. Pontzen and Mr. R. W. Swain.

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (joint meeting with the Agriculture Group, at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Meeting on "Crop Production for Processing".

## Wednesday, January 18

GEOLOGICAL SOCIETY, VOLCANIC STUDIES GROUP (at Burlington House, Piccadilly, London, W.1), at 2 p.m.—Annual General Meeting.

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 3 p.m.—"The Admiralty Chart".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. J. L. Monteith: "Local Differences in the Attenuation of Solar Radiation Over Britain". Mr. G. Stanhill, Mr. G. F. Hofstede and Mr. J. D. Kalma: "Radiation Balance of Natural and Agricultural Vegetation"; Mr. N. Thompson: "Short-range Vertical Diffusion in Stable Conditions".

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 5 p.m.—Dr. M. Caplin: "The Control of Tuberculosis".\*

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Discussion Meeting on "William Allen Whitworth and a Hundred Years of Probability" opened by Dr. J. O. Irwin.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. M. V. Wilkes, F.R.S.: "Multi-Access Computer Systems".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. G. N. Gould: "Cattle Breeding and Related Diseases".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Dr. B. J. Mason, F.R.S.: "The Generation of Cloud Electricity".

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (in the Physics Department, Imperial College, London, S.W.7), at 6.30 p.m.—Mr. L. A. Tysall and Mr. J. Van Westrenen: "Evaluation for Electrodeposition of Recently Developed Water Soluble Epoxy Esters".

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "Automatic C.H.N. Analyzers".

INSTITUTE OF FUEL (at Calor Gas (Distributing) Co., Calor Gas House, Key West, Slough, Bucks), at 7 p.m.—Mr. I. Carter: "LPG-Air Plants".

SOCIETY OF DYERS AND COLOURISTS (at the Waldorf Hotel, Aldwych, London, W.C.2), at 7 p.m.—Dr. T. J. Elliott: "Colour in Cosmetics".

## Thursday, January 19

SOCIETY FOR ANALYTICAL CHEMISTRY, AUTOMATIC METHODS GROUP (at the Wellcome Building, Euston Road, London, N.W.1), at 3 p.m.—Meeting on "Computer Applications in Analytical Chemistry".

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. P. M. Harris and Mr. D. V. Jackson: "Investigations into the Recovery of Niobium from the Mirna Hill Deposit"; Mr. L. D. Airey: "Introduction of the Cascade Method of Continuous-Retreat Open Stopping at Mufulira Copper Mines, Ltd., Zambia".

LINEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. J. G. Hawkes: "Botanical Exploration in Argentina".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. G. W. Mackey: "Group Representations and Number Theory".

INSTITUTE OF PETROLEUM, EXPLORATION AND PRODUCTION GROUP (at 19 New Cavendish Street, London, W.1), at 5.30 p.m.—Prof. W. D. Gill: "Carbon Ratio Theory as Applied to the British Isles".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. E. H. Nelson: "New Developments in High-Pressure Discharge Lamps".

UNIVERSITY OF LONDON (at the Institute of Child Health, Gullford Street, London, W.C.1), at 5.30 p.m.—Dr. M. F. Oliver: "Control of Hyperlipidaemia in Relation to Ischaemic Heart Disease". (Third of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)\*

UNIVERSITY OF LONDON (at the School of Pharmacy, 29-39 Brunswick Square, London, W.C.1), at 5.30 p.m.—Prof. A. R. Battersby: "Biogenesis of Alkaloids". (Further lecture on January 20.)\*

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. M. R. Pollock: "The Changing Concept of Organism in Microbiology. I. The Cell as a Molecular Mosaic".\*

CHEMICAL SOCIETY (at the Royal Institution, Albemarle Street, London, W.1), at 8 p.m.—Prof. L. G. Sillén (Royal Institute of Technology, Stockholm): "How have Sea Water and Air got their Present Composition?".

INSTITUTION OF ELECTRICAL ENGINEERS (joint discussion meeting with the I.E.R.E. Computer Group, at the I.E.R.E., 8-9 Bedford Square, London, W.C.1), at 6 p.m.—Meeting on "Practical Applications of Computer Programmes in Electronic Engineering".

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDINGS MATERIALS GROUP (joint meeting with the Institution of Highway Engineers, at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. C. H. Peters: "The Maintenance of Concrete Roads".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Symposium on "The Clinical and Biochemical Aspects of Thalassaemia" opened by Dr. Ph. Fressas and Dr. E. R. Huehns.

## Friday, January 20

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. M. R. Pollock: "The Changing Concept of Organism in Microbiology. II. Inter-cellular Exchange of Nucleic Acid".\*

## Monday, January 23

INSTITUTE OF ACTUARIES (in Staple Inn Hall, High Holborn, London, W.C.1), at 5 p.m.—Mr. M. G. Hall and Mr. D. Weaver: "The Evaluation of Ordinary Shares Using a Computer".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. Bryan Robertson, O.B.E.: "The Arts" (second of four Cantor Lectures on "Some Aspects of the U.S.A. To-day").

UNIVERSITY OF LONDON (at the Institute of Diseases of the Chest, Brompton Hospital, London, S.W.3), at 6.15 p.m.—Dr. M. C. Joseph and Dr. G. A. Miller: "The Special Problems of Paediatric Cardiology".\*

INSTITUT FRANÇAIS DU ROYAUME-UNI (at Queensberry Place, London, S.W.7), at 8.15 p.m.—Programme of French Scientific Films.\*

## Monday, January 23—Thursday, January 26

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2)—Conference on "Acoustic Noise and Its Control".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

HEAD (with suitable academic qualifications and preferably some Industrial experience) OF THE DEPARTMENT OF CHEMISTRY—The Clerk to the Governors, Woolwich Polytechnic, Wellington Street, London, S.E.18 (January 20).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF COMPUTATIONAL AND STATISTICAL SCIENCE—The Registrar, Liverpool University, Liverpool, 3, quoting Ref. 336 (January 21).

RESEARCH ASSISTANT (graduate in geography or physics and an interest in synoptic meteorology and/or historical climatology) in CLIMATOLOGY in the DEPARTMENT OF GEOGRAPHY—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (January 21).

RESEARCH ASSISTANT (with a good honours degree in geography or a related field and some experience in field surveying and mathematical geography) in the DEPARTMENT OF GEOGRAPHY to work on the bathymetric survey of Loch Leven, Kinross, under the direction of Dr. R. P. Kirby—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (January 23).

UNIVERSITY LECTURER (preferably with some interest in the biometrical use of computers) in the DEPARTMENT OF BIOMATHEMATICS—Prof. M. S. Bartlett, Department of Biomathematics, The University, 7 Keble Road, Oxford (January 23).

ASSISTANT (graduate in veterinary science, pharmacology, pharmacy or other appropriate discipline) in VETERINARY PHARMACOLOGY—Secretary of the University Court, The University, Glasgow (January 27).

LECTURER or ASSISTANT LECTURER (preferably with research interests in analysis) in PURE MATHEMATICS—The Registrar, University of York, Heslington, York (January 27).

LECTURER and ASSISTANT LECTURER in the MECHANICS OF FLUIDS in the FACULTY OF SCIENCE—The Registrar, The University, Manchester, 13, quoting Ref. 254/68/Na (January 28).

SENIOR LECTURER (with special experience of both the clinical and laboratory aspects of haematology) in HAEMATOLOGY—The Secretary, The University, Aberdeen (January 28).

LECTURER or SENIOR LECTURER in PATHOLOGY—The Registrar, The University, Leeds, 2 (January 30).

ASSISTANT LECTURER or LECTURER in the DEPARTMENT OF APPLIED MATHEMATICS AND MATHEMATICAL PHYSICS—The Acting Registrar, University College of South Wales and Monmouthshire, Cardiff (January 31).

LECTURER or ASSISTANT LECTURERS in ELECTRONIC MATERIALS in the SOLID-STATE ELECTRONICS GROUP of the DEPARTMENT OF ELECTRICAL ENGINEERING—The Registrar, The University of Manchester Institute of Science and Technology, Manchester, 1 (January 31).

**RADIATION PROTECTION OFFICER** (physicist) throughout the University and Hospitals—The Secretary, The University, Aberdeen (January 31).

**SUPERINTENDING TECHNICIAN or SENIOR TECHNICIAN** (experienced in laboratory and workshop practice and supervision, and capable of detail design work and the manufacture and maintenance of laboratory equipment) in the DEPARTMENT OF CIVIL ENGINEERING, Ahmadu Bello University, Northern Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (January 31).

**SENIOR LECTURER** (pure mathematician) in MATHEMATICS—The Assistant Secretary, The London School of Economics and Political Science, Houghton Street, London, W.C.2 (February 2).

**LECTURER** (trained teacher, with an honours or higher degree in science, and successful experience in the teaching of science) in EDUCATION (Science Teaching) at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, February 3).

**LECTURER or SENIOR LECTURER in PHILOSOPHY**—The Registrar, The University, Keele, Staffordshire (February 4).

**SENIOR LECTURER or LECTURER** (with a degree in mechanical engineering from a recognized university and experience in teaching or research or in industry) in MECHANICAL ENGINEERING at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 4).

**UNIVERSITY LECTURER** (preferably interested in studies of systematics and variation with reference to genetics, cytology, ecology, plant geography or the origins of cultivated plants) in BOTANY—The Administrator, Botany School, University of Oxford, South Parks Road, Oxford (February 5).

**CHAIR OF APPLIED MATHEMATICS** at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 6).

**READER** (with special interests in mathematical physics or in some other branch of applied mathematics) in MATHEMATICS—The Registrar, Beverley Farm, The University, Canterbury, Kent, quoting Ref. A.31 (February 7).

**LECTURER in CHEMISTRY** (Organic, Physical or Inorganic) at University College, Dar es Salaam, University of East Africa—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 9).

**CHAIR in HUMAN GENETICS in the FACULTY of MEDICINE**—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (February 10).

**LECTURER** (with full training in psychology, special training or experience in clinical psychology, and preferably holding a postgraduate qualification in clinical psychology) in CLINICAL PSYCHOLOGY at the University of Queensland, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, February 10).

**CHAIRS (2) OF ELECTRONIC and ELECTRICAL ENGINEERING**—The Registrar, The University, Sheffield, 10 (February 11).

**LECTURER in NUCLEAR PHYSICS, and a LECTURER in THEORETICAL PHYSICS**—The Secretary, University of Lancaster, University House, Bailrigg, Lancaster, quoting Ref. L.197/A (February 11).

**CHAIR OF PSYCHIATRY**—The Registrar, The University, Sheffield, 10 (February 13).

**DIRECTOR** (with special interests in fisheries research) OF THE INSTITUTE OF MARINE BIOLOGY and OCEANOGRAPHY, Fourah Bay College, The University College of Sierra Leone—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 15).

**ASSISTANT LECTURERS, LECTURERS or SENIOR LECTURERS in GEOGRAPHY** at University College, Dar es Salaam, University of East Africa—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 16).

**SENIOR LECTURER** (preferably with an interest in device physics, physical electronics or materials science) in ELECTRICAL ENGINEERING at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 17).

**CHAIR OF ANATOMY** at the University of Tasmania, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Tasmania and London, February 28).

**CHAIR OF PHARMACEUTICAL CHEMISTRY or CHAIR OF PHARMACEUTICS** at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, February 28).

**LECTURER in ZOOLOGY** at the University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (March 1).

**SENIOR LECTURER in GENETICS** at the University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (March 1).

**LECTURER in CLINICAL BIOCHEMISTRY in the DEPARTMENT of PATHOLOGY**, University of Hong Kong—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Hong Kong and London, March 15).

**CHAIRS (3) OF BIOLOGY** in the Research School of Biological Sciences in the Institute of Advanced Studies, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

**RESEARCH PHYSICIST** (preferably with a higher degree and relative experience) in the PHYSICS DEPARTMENT to undertake investigation of electron scattering using a 400 kV electron diffraction camera with recently constructed energy analysis facility—The Assistant Bursar (Personnel), University of Reading, Reading, Berkshire.

**SENIOR DEMONSTRATOR** (with an honours or master's degree or equivalent qualifications) in the DEPARTMENT of PHYSICS, to take responsibility for the organization and maintenance of first, second or third year undergraduate laboratories—Prof. C. E. Challis, Head, Department of Physics, The University of Calgary, Calgary, Alberta, Canada.

**Recreational Land-Use**. Pp. 6. (London: The Ramblers' Association, 1966.) [2810]

The Royal Observatory, Edinburgh. Publications—Vol. 5, No. 10: Three-Colour Photometry of Southern Galactic Clusters. III: NGC 6187. By M. T. Brück and M. J. Smyth. Pp. 195-232. (Edinburgh and London: H.M. Stationery Office, 1966.) 8s. net. [2810]

Ministry of Agriculture, Fisheries and Food. Domestic Food Consumption and Expenditure: 1964, with a Supplement giving Provisional Estimates for 1965. Annual Report of the National Food Survey Committee. Pp. x+162. (London: H.M. Stationery Office, 1966.) 16s. 6d. net. [2810]

Planning, Vol. 32, No. 498 (November 1966): Problems Facing the Teaching Profession. Pp. 193-236. (London: Political and Economic Planning, 1966.) 6s. [3110]

Perfumes Against Pests. Pp. 43. (Braintree, Essex: Henry Doubleday Research Association, 1966.) 3s. 6d. [3110]

Ambassade de France, Service de Presse et d'Information. French Agriculture. Pp. 14. (London: Ambassade de France, Service de Presse et d'Information, 1966.) [3110]

## Other Countries

National Academy of Sciences—National Research Council. Sub-committee on Radiochemistry. NAS-NS 3058: The Radiochemistry of Plutonium. By George H. Coleman. Pp. vi+184. (Springfield, Virginia: Clearinghouse for Federal Scientific and Technical Information, N.B.S., U.S. Department of Commerce, 1966.) 82. [2710]

United States Department of the Interior: Geological Survey. Water-Supply Paper 1806: Ground-Water Resources and Geology of Northern and Central Johnson County, Wyoming. By Harold A. Whitcomb, T. Ray Cummings and Richard A. McCullough. Pp. v+99+plates 1 and 2. (Washington, D.C.: Government Printing Office, 1966.) [2710]

Applications Manual for Computing Amplifiers for Modelling, Measuring, Manipulating, and Much Else. Pp. 116. (Dedham, Mass.: Philbrick Researches, Inc., 1966.) [2710]

The Lower Pleistocene of the Central Jordan Valley—The Excavations at 'Ubeidiya, 1960-1963. Geological Report on the Lower Pleistocene Deposits of the 'Ubeidiya Excavations. By L. Picard and U. Baida. Pp. 39+8 plates. 25s. On the Vertebrate Fauna of the Lower Pleistocene Site 'Ubeidiya. By G. Haas. Pp. 68+14 plates. 30s. Archaeological Excavations at 'Ubeidiya, 1960-1963. By M. Stekela. Pp. 32+42 plates. 37s. 6d. (Jerusalem: The Israel Academy of Sciences and Humanities, 1966. Distributed by H. A. Humphrey, Ltd., London, W.C.1.) [2710]

United States Department of the Interior: Geological Survey. Professional Paper 431-E: Geology and Mineral Resources of the Monievade and Rio Piracicaba Quadrangles, Minas Gerais, Brazil. By Robert G. Reeves. Pp. iv+68+plates 4-7. (Washington, D.C.: Government Printing Office, 1966.) [2810]

Institut Royal des Sciences Naturelles de Belgique. Mémoires. No. 154: La Flore et la Faune du Bassin de Chasse d'Ostende (1938-1962). I: Topographie et Nature du Fond. Par Eugène Leloup. II: Étude Écologique et Floristique. Par Ludo Van Meel. Pp. 189. Deuxième Série, Fasc. 79: Documents Paléobotaniques pour l'Étude du Houiller dans le Nord-Ouest de l'Espagne. Par E. Stockmans et Y. Willere avec la collaboration de C. de la Vega. Pp. 106+38 planches. (Bruxelles: Institut Royal des Sciences Naturelles de Belgique, 1966.) [2810]

World Health Organization. Technical Report Series, No. 341: Principles for Pre-Clinical Testing of Drug Safety—Report of a WHO Scientific Group. Pp. 22. (Geneva: World Health Organization; London: H.M. Stationery Office, 1966.) 2 Sw. francs; 3s. 6d.; \$0.60. [3110]

National Academy of Sciences—National Research Council. Publication No. 1402: Scientific Aspects of Pest Control—a Symposium arranged and conducted by the National Academy of Sciences—National Research Council, at Washington, D.C., February 1-3, 1966. Pp. xi+470. (Washington, D.C.: National Academy of Sciences—National Research Council, 1966.) \$6. [3110]

National Science Foundation—Office of Science Information Service. NSF-66-17: Current Research and Development in Scientific Documentation, No. 14. Pp. viii+662. (Washington, D.C.: Government Printing Office, 1966.) 82. [3110]

Bulletin of the American Museum of Natural History. Vol. 134, Article 1: Hybridization in Meadowlarks. By Wesley E. Lanyon. Pp. 1-26+8 plates. (New York: American Museum of Natural History, 1966.) 82. [3110]

India: Central Fuel Research Institute. Report of the Director for the year 1963-64. Pp. v+108. (Jalgaon, Dhanbad, Bihar: Central Fuel Research Institute, 1966.) [3110]

India: Council of Scientific and Industrial Research. Annual Report of the Research Survey and Planning Organization, covering the period January 1965 to March 1966. Pp. 23. (New Delhi: Research Survey and Planning Organization, 1966.) [3110]

Conseil Permanent International pour l'Exploration de la Mer. Service Hydrographique, Charlottenlund-Slot, Danemark. ICES Oceanographic Data Lists. 1960, No. 2. Pp. xxii+166. 25 Kr. 1960, No. 5. Pp. xv+132. 20 Kr. (Copenhagen: Andr. Fred. Hest et Fils, 1966.) [3110]

The Carlsberg Foundation's Oceanographical Expedition Round the World 1928-30 and previous "Dana" Expeditions. "Dana" Report No. 68: *Bathyprius danae*—a New Genus and Species of Alepocephaliform Fishes. By N. B. Marshall. Pp. 10. "Dana" Report No. 69: The Bathypelagic Macrourid Fish, *Macrourus inflaticeps*, Smith and Radcliffe. By N. B. Marshall and A. Vedel Tåning. Pp. 6+1 plate. (Copenhagen: Andr. Fred. Hest et Fils, 1966.) 6 Kr. [3110]

## SPILLING BLOOD WITHOUT MESS

THE way in which the University Grants Committee has set about rationalizing the schools of agriculture at British universities is an important innovation, but it is not yet time for the defenders of academic freedom to rush to the barricades. Distinguished ex-presidents of the National Farmers' Union may feel themselves threatened, but there is no reason why academics should interpret the plan to do something about agriculture as a sinister plot against the freedom of the universities. On the face of things, at least, the University Grants Committee has a good case. Although by resting the case for a simpler pattern of undergraduate teaching on a report of a committee which finished deliberating more than two decades ago the U.G.C. may be somewhat vulnerable, the size of the demand for graduate agriculturists is not really the crucial consideration. The strongest argument in favour of rationalization is that the twelve schools of agriculture in Britain produce an average of fewer than forty graduates each year, and many of these are labelled diversely as horticulturists, foresters and the like. The chances are high that there is a more efficient way of producing graduate agriculturists.

But if the case for rationalizing in agriculture is strong, it does not follow that the U.G.C. should be cheered on whenever it conceives of a plan to make the organization of universities simpler, cheaper or more efficient. On the contrary, it will need to be watched with extra care now that its efforts to mould the pattern of teaching have gone beyond the discouragement of unwanted innovation to the closing down of unwanted institutions. It is also, however, fair to recognize that the U.G.C. has some difficult problems to contend with. The need to make better use of the facilities which exist—people and plant—has if anything been aggravated by the frequently uncritical acceptance of the assumption of the Robbins Report that a bigger university population must mean more universities on the traditional pattern. In retrospect, there is bound to be a conflict between the reasonable wish of the existing universities, new and old, to teach what they want to teach, and the plain fact that teaching must be on a sufficiently big scale if teachers and students are to get the best out of it. One way out of many present difficulties would be the emergence of a regional pattern of federation for British universities, but that is obviously a distant goal or even just a pipe-dream. Of necessity, the U.G.C. is forced to act where opportunities occur.

But is it acting wisely? Is it sensible to persuade some universities to stop doing things some of them at least want to continue? Might it not be better to take a more positive line, and to encourage the concentration of teaching at a smaller number of centres

by channelling extra funds in the directions that seem most profitable? Experience elsewhere, and particularly in the United States, has shown how the establishment of what are called centres of excellence in particular fields can serve to force the pace of innovation and improvement. But they could also help to concentrate teaching in a smaller number of institutions. In the particular circumstances of higher education in agriculture at British universities, there may be reasons for thinking that the supply of graduates is adequate, but in the nature of things nobody can be sure that there is no room for valuable changes in the character of teaching. In other words, the U.G.C. might have done a service to agriculture and to its own reputation by looking for a more positive way of attaining its reasonable ends.

There remains the question of who should say what ends are worth attaining. In deciding on the rationalization of agriculture, the U.G.C. seems to have acted off its own bat. Prompted, no doubt, by the need to make the best of what funds it has to spend, the committee has found what seems to be a field in which economies are possible. No doubt the subject panel responsible for agriculture has helped enormously with drafting the detailed proposals circulated to the universities affected, but responsibility rests with the main committee of the U.G.C., and cannot easily be questioned. There are several risks in this procedure, not the least of which is that the U.G.C. may sometimes be wrong. In the long run, it should be for the universities as such, and not for the U.G.C., to say how best the pattern of university teaching should be made to meet the reasonable needs identified by the U.G.C. The one who pays the piper may call the tune, but it is not for him to decide just how it should be played. It does not help that the U.G.C. seeks advice from a panel of academics appointed for the purpose. Even if the U.G.C. were to relax its baffling unwillingness to make public the membership of its subject panels, the plain fact is that those who give advice must act as private individuals and not as representatives of the universities. What is needed is some procedure by means of which the U.G.C. could make a case for economy to the universities as a whole, and in which the universities could work out among themselves the best way of responding. This is yet another burden that must eventually be carried by the Committee of Vice-Chancellors and Principals.

## POLITICAL SCIENTISTS

THE activities of science and technology have not become political issues as quickly in Britain as in the

United States, so that there will be a wide welcome for the way in which the *Political Quarterly* has given over its spring issue entirely to a symposium on what it calls the politics of science. Even those who consider that the whole enterprise has somehow fallen short of the declared objective of helping "to reconcile the interests of science with the needs of society" will find pleasure in much of what the contributors have to say. Dr. H. M. Finneston is particularly worth reading on the relationship—or lack of relationship—between the universities and industry; in the present climate, what he has to say will make more friends than enemies. Yet the overall impression left by this symposium is of a miscellany of arguments advanced by different people from different points of view. Only Professor J. D. Bernal comes close to a definition of the kinds of questions on which political decisions can critically affect the health, or otherwise, of science and technology—the scale on which resources should be allocated to research and development, the importance that should be attached to defence research and the allocation of resources to higher education, for example—and he is compelled on several occasions to offer not answers but reasons why answers will be difficult to find. Nobody should be surprised if the readers of the *Political Quarterly* are persuaded by the experience that the concept of the politics of science is nebulous, to say the best of it.

To say this is not to suggest that the political implications of science and technology, and the scientific implications of politics, are unimportant or non-existent, but that the relationship between them is a good deal more complicated than is commonly allowed. Failure to acknowledge the full complexity of the interaction is the root of a good many fashionable fallacies. Thus there is no certain assurance that the best way of obtaining a greater stock of skilled engineers is to introduce more applied science (or more science of any kind) into the secondary schools. Although there is no doubt that science and technology are at the roots of the modern industries with which advanced societies create wealth, it does not follow that more research and development will bring more wealth. In Britain, for example, there is at least a case for saying that the comparatively slow rate of economic growth in the past fifteen years is not a consequence of deficiencies in technology but of a failure to exploit new techniques of management to the full. (On this reading, the brain drain is an empirical proof of a surplus of scientists and engineers, which is not as outrageous an interpretation as it may seem; scientists and engineers would not emigrate in such large numbers if their employers paid them enough to stay at home.) Certainly there is no case for thinking that all research and development is equally valuable, which implies that the gross yardsticks inevitably used for comparing the scale of scientific effort in different places may not be reliable. The *Political Quarterly* itself argues that research aimed at prestige and not economic benefit is a waste of money, which only goes to show that accountants have very little to say about the scale

on which efforts should be deployed. It follows that politicians should not be surprised if their reading of this symposium leaves them with the impression that the politics of science is not a simple monster but a hydra. That is not an illusion but the truth.

## HUNTING THE QUASAR

THE hunt for the quasar goes on. This week (page 239) it is Professor McCrea. Last week it was Professor McVittie, Dr. Stabell (*Nature*, 213, 133) and Dr. Verschuur (*ibid.*, 164). Next week—who knows? The only certainty is that it will be some time before there is a simple answer to one of the most teasing problems for several decades. At least a part of the reason for interest in quasars is that experimental information is so meagre that people are necessarily hard pressed to tell a good answer from one that is merely plausible. It is just within the bounds of possibility that one of these days somebody may point to some well established truth with such conviction that everybody will know what quasars are.

In the meantime, it is only seemly to recall that theorists are rarely so much at a loss as the cosmologists are now when confronted by the observational evidence on quasars. For four years it has been plain that quasars could not be written off as intense radio galaxies, if only because not all of them are radio sources. Their frequently gigantic red-shifts imply great distance, but their variability from year to year and even from month to month implies dimensions which are small (in light years or light months) and therefore, probably, a location somewhere within the local galaxy. How is this apparent conflict to be resolved? In the long run there will be data substantial enough to guide people more certainly to a conclusion. But it is also possible that there may be more to wring out of the observations already on record, which is why there is a continual search for some suggestive irregularity in the data—anisotropy, perhaps, or a significant departure from the relationship between the brightness of quasars and their frequency that would be expected from the hypothesis that the universe is always everywhere the same. This, too, is why people are searching for ways in which comparatively familiar cosmological bits and pieces could be made to behave like quasars. Some theories involve comparatively local quasars, and then have to deploy great ingenuity on an explanation of how spectral lines can be shifted towards the red, presumably as a relativistic consequence of a gravitational attraction, without the celestial object concerned being so dense that it prevents the escape of radiation. Other theories involve more distant objects. But nobody knows which model will succeed, and how soon. And nobody knows how radical a revision of accepted doctrines a decent model of quasars will require. If astronomers should fail to sleep for excitement—or even from anxiety—society should indulge them.

## NEWS AND VIEWS

### What Next at Naples?

A REORGANIZATION of the financial basis of the Naples Zoological Station is now being considered by the learned societies which at present help to support the station by means of annual subscriptions towards the maintenance of "tables" at the laboratory. Hitherto the annual subscription has been \$3,000 a table, for some reason translated into sterling as £1,200. Under the new scheme, subscriptions would be increased by roughly 25 per cent from June 1, 1967. In addition, it is now suggested that those institutions elsewhere wishing to contribute the equivalent of 50 million lire to the annual cost of the station would be entitled to a seat on the Administrative Council which is responsible for the government of the station through its present director, Dr. Peter Dohrn. By all accounts, these proposals are welcomed by the academies principally concerned, partly because it is considered that access to the station would be good value for money even at a higher rate, and partly because a stronger international financial basis of operations would help to ensure the continued international character of the work at Naples.

Altogether, rather more than 60 tables are maintained at Naples by institutions from fifteen countries. Various Italian sources between them make up the largest volume of support (19 tables), with Germany (12 tables) and the United States (10 tables) next in order. The United Kingdom, through the Royal Society, maintains four tables. Although the maintenance of a table is chiefly a way of shouldering a share of the cost of running the station, the academies which contribute funds are also responsible for allocating places at the laboratory to people from their own countries. Naturally enough, marine biologists of various kinds account for much of the demand on facilities at the laboratory, which include an elaborate system of fishing to recover specimens and an ample supply of Mediterranean water, but physiologists and others concerned to work with fresh marine material are also drawn there. So, too, are a number of scientists wishing to make use of the splendid library at the station. Short visits of a month or so are encouraged. The station will provide basic needs, but visitors have usually to bring special items of equipment from their own laboratories. In the past few years, reconstruction of buildings at the station has been supported by government sources in the United States, the Federal German Republic, the United Kingdom and the Italian Government as well as by the Volkswagen Foundation.

Although the proposed increase in contributions is probably well accounted for by increases of costs, it is also in some quarters regarded as a defence against the view, sometimes expressed in Italy, that the zoological station should be allowed to grow into an Italian equivalent of the national laboratories such as those at Plymouth and at Woods Hole, Massachusetts. On the face of things, of course, it is anomalous that one of the most renowned laboratories in Italy should have been founded by a German (the grandfather of the present director) and should be supported by and run

for scientists from a dozen countries. Elsewhere it is argued that the station is an invaluable centre for international collaboration, possibly unique. Its value in this respect is only likely to be enhanced by the siting of an international laboratory of genetics and biophysics at Naples.

The recent history of the zoological station has also been disturbed by what are sometimes described as "labour difficulties" among the technical staff. In part, these probably reflect some of the economic difficulties of carrying out advanced scientific work in the south of Italy, and recent visitors to the station speak well of the quality of the assistance which they have received. Another frequent visitor points out that troubles of various kinds are inseparable from Naples and are "always desperate, never serious".

### Squeeze on Universities

THE University Grants Committee has embarked on a programme of what it calls "rationalization in the teaching of agriculture at British universities". Although it has already provoked a brisk if predictable protest from three members of the House of Lords on the grounds that the national importance of agriculture has not been fully considered, the committee has probably fixed its eyes on a more distant target, and is probably interested to see whether it can work out procedures whereby rationalization could be carried out elsewhere in the academic spectrum.

In a letter to *The Times* on January 16, Lords Abergavenny, Cornwallis and Netherthorpe said that the universities of Leeds and Cambridge had been "invited" to give up their degree courses, and that the schools of horticulture at Reading and Nottingham are similarly threatened. These public signs of pressure seem to be the tips of a substantial iceberg. The U.G.C. says that it wrote before the beginning of the present academic year to three universities at which degree courses in agriculture were considered expendable, to a number of others at which there are schools of horticulture the independent existence of which is not thought to be essential, and to other universities where the present diversity of courses with titles such as "soil science" and "agricultural economics" is considered altogether too rich. As yet most of the universities concerned are still nursing the insult to their pride in silence. According to the U.G.C., all universities are keen on rationalization, but somewhere else than on their own premises.

The case for making a start on agriculture rests, in part, on the Bosanquet Committee which, at the end of the Second World War, considered that the production of graduates in agriculture from British universities might well be greater than the demand. The U.G.C. considers that the few deficiencies which the Bosanquet Committee pointed out have now been made good, but that the broad adequacy of production of graduates in agriculture remains. In any case, the argument goes, the plan is to concentrate teaching in agriculture on "fewer but stronger" schools. According to the U.G.C., there is no intention to reduce the numbers of graduates leaving the universities. Agricultural undergraduates have, however, been a declining proportion of the entire student body in the past decade. In 1964-65 there were 1,701 of them, or 1.5 per cent of the total, compared with 2.6 per cent

of the student population a decade earlier. The number of first degrees works out at around 450 a year, and the U.G.C. says that this is enough to satisfy not only the demand for trained agriculturists in Britain but that from overseas as well.

On the machinery for making these decisions, the U.G.C. says that the main committee must be held responsible for all decisions, right or wrong, although in this case the committee did consult the subject panel responsible for agriculture whose chairman is Sir Harold Sanders, now deputy chairman of the U.G.C. and who was professor of agriculture at the University of Reading from 1944-54 and afterwards chief scientific adviser to the Ministry of Agriculture. According to a spokesman of the U.G.C., the Committee of Vice-Chancellors and Principals has been informed of the scheme for rationalizing agriculture, though it has not been embarrassed with the details.

## Cost of Learning

THANKS to Governor Ronald Reagan, people far from California now know that his state offers its citizens free education at college and university. Not that Mr. Reagan, a fortnight in office, is proud of California's century-old record of free university tuition. He wants to keep his Republican campaign promise to reduce government spending and proposes to cut the university's \$240 million annual budget by 10 per cent. To recoup these losses, he suggests that the university—with nine campuses and 80,000 students—and the network of state colleges—with about 127,000 students—should charge tuition fees of several hundred dollars a year. If this were to happen—and it is by no means certain that it will—the new fees could keep away as many as 20,000 new students next autumn. In turn, the state's admirable Master Plan for Higher Education under which the university and college network expand with the population would be brought to a halt.

To be accurate, higher education in California is not absolutely free of charge. Residents of the state pay about \$240 a year at the university in various required fees. Those from outside its borders pay almost as much as they would at a private university—about \$1,000. The state's Finance Director, who seems to be the Iago of the plot, thinks that perhaps too many Californians are going to university just because it is so cheap. Any graduate of a high school or other secondary school is eligible for the university if he has a *B* average. The state colleges are even more catholic: they take in secondary school graduates with a *C* plus average. These colleges might be harder hit than the university by an imposition of tuition fees, for their intending students presumably are more easily discouraged than the more gifted ones who are hell-bent for university.

With the prospect of political storms on the way, people are already wondering if the university's branch at Berkeley will be able to hold its teaching staff. The mood of the undergraduates at Berkeley, following the celebrated riots of recent years, is said to be restless, even anarchic. The Reagan assault on the university's independence could set off another round of mass demonstrations, sit-ins and strikes which could in turn drive away those young teachers looking for a place to do serious and serene work.

While California's problems are exotic, state-aided colleges and universities throughout the United States are finding themselves forced to raise their traditionally low fees. Some of these are still surprisingly modest, even by British standards. At the University of Texas, a Texan student pays only \$100 a year. Someone from outside the state must pay \$703. New York's prestigious state university at Cornell is more expensive—about \$600 for a New Yorker, about \$1,000 for outsiders. The University of Hawaii generously charges the same fee—\$232.50—to those from the islands and those from the mainland. Tuition charges are relatively low for outsiders at the University of Arkansas (\$470), the University of Ohio at Bowling Green (\$550) and Louisiana State University (\$620). The cost of tuition at Harvard and Yale works out at \$1,800 a year with roughly the same amount for board and lodging. Only the universities of Idaho and Connecticut have somehow been able to resist the temptation—or the necessity—of charging for higher education.

## British Fees Go Up

IN Britain, too, tuition fees are to be increased in the interests of the economy, and, it is claimed, the balance of payments. The Department of Education and Science, which says that the tuition fees for university students are about £70 per year, and for technical college students £30-£40 per year, intends to increase them to £250 and £150 respectively. A furore has been caused because the increase is to apply only to students from overseas. Foreign students already embarked on courses in Britain will not be quite so brutally treated; their fees are to increase by £50 per year.

Critics of the proposals say that more than 70 per cent of the foreign students in Britain come from developing countries, and will have the utmost difficulty in finding the extra money. Some, who arrive without qualifications at British technical colleges to qualify themselves for British universities, will be faced with increases amounting to £760 over five years. Critics also claim that the saving the government hopes to make, £5m, is pure speculation, and that the moves made by the government to offset the additional cost will apply only to a minority of students already in residence, and not at all to those arriving for the academic year 1967-68. A more philosophical point is that the assistance will only apply to students sponsored by governments and government organizations, and not to those who come on their own initiative.

Abroad, the proposals may seem to be a crude way of summarily reducing immigration into Britain and assistance from Britain to developing countries. Certainly the fuss seems hardly worth the putative failing; the government may well be shocked by the intensity of the reaction, which shows no signs of dying down. As in California, students are likely to make the most noise, but they may well be supported by some academics.

## Forward by Degrees

SUBSTANTIAL progress is reported by the Council for National Academic Awards for its second year of operation up to September 30, 1966. The Council has considered 104 courses, and has approved 66, most of them honours degree courses. It has also announced

the regulations for higher degree courses, leading to the M.A., M.Sc., Ph.D. and M.Phil. degrees. The first full-time postgraduate course, for an M.Sc. in Applied Solid State Physics at Brighton College of Technology, has been approved, and others are in the pipeline. The Council has also set up several new subject boards as well as a committee to consider proposals for degree courses in education from colleges of education and technical colleges. It has also adopted its own academic dress, and opens its report with a drawing of its armorial bearings. It is beginning to look like an established institution.

The Council has clearly been thinking deeply about the White Paper setting out the plan for polytechnics and other colleges, but the new report says little about this. It is content to record the assumption that the polytechnics will get the staff, accommodation and equipment they need, and its concern that the polytechnic policy of concentrating resources will not prejudice students following C.N.A.A. courses. The Council has obviously been greatly encouraged by the recommendation of the Committee of Vice-Chancellors and Principals, which recommended that universities should regard holders of C.N.A.A. degrees on the same footing as holders of university degrees.

## More from Medlars

THE United States Library of Medicine has stored on magnetic tape the vast quantity of information which is used each year to produce the *Index Medicus* and has for some months been disseminating this information through the Medical Literature Analysis and Retrieval System (MEDLARS). One way in which this can be done is in the form of specialist bibliographies covering topics of interest to individuals or groups of research workers, and this service has now become available to British scientists through the National Lending Library.

The bibliographies are of three kinds. Some are firmly established, such as the *Index of Rheumatology* and the *Index to Dental Literature*; these are published regularly by the National Library of Medicine and cost money. Others are still at an experimental stage, and are being distributed free to selected groups of scientists in return for 'feedback' in the form of information and criticism. The third type of bibliography is tailored to suit the needs of the individual, who defines his sphere of interest by means of a word profile which can be fed into a computer. The computer then produces a list of titles and bibliographical details, which are set in type by GRACE (Graphic Arts Composing Equipment). The system demands little of the research worker; all he has to do is to produce a word profile (some librarians, trained by the National Lending Library, can assist in this) and send it to the NLL, which will send free of charge a bibliography covering research in his area of interest since 1963.

This open-handedness can scarcely last for ever. The cost of the input end of the system is carried by the Department of Health, Education and Welfare in the United States, while in Britain the running costs of the system are paid by the Science Research Council. When the experimental period ends in 1968, it will have to be decided whether the benefits of the system justify its cost. So far British experience indicates that it is a useful service; one worker said that of the

295 titles selected by the computer 59 were useful to him. To have found these 59 papers without the computer would have meant reading 17,500 references. It also seems that however well read an individual may be, the computer will turn up titles he had not come across before. Whether the costs of the service are justified will only be known when some estimate of its usefulness can be made; British medical research workers are therefore being urged to make use of the service, and then to tell the National Lending Library what they think of it.

## Synonyms for Chemists

CHEMISTS should be less frequently at a loss for words now that the Chemical Abstracts Service of the American Chemical Society has published the word guides which are intended to help those who would extract information from the reels of magnetic tape on which information about the titles of chemical articles in the literature is being stored. The lists now available are more than mere thesauri in the sense of Roget, for the groups of words associated with each main entry in the lists are allocated to categories intended to give some sense of the character of the relationship between words in a pair. Two word guides are available, one for use with the *Chemical Titles* tapes and one with the magnetic tapes called *Chemical-Biological Activities* on which are stored the titles of articles in some 600 periodicals and short abstracts as well.

As well as straightforward synonyms for words, the guides include terms which are both broader and narrower, together with some which are merely close relations. For example, the chemist who looks up "Hamster" will find that the terms "Animal" and "Rodents" are both broader terms, that "Chinese Hamster" is a narrower term, that "Rat" is a related term and "*Cricetus cricetus*" is a synonym. The importance of the word guides stems from the way in which machine retrieval systems require the potential user to specify the area of his curiosity by means of words or word stems. Computers will pick out titles in which the specified words appear, either singly or in combination with others. One obvious difficulty is that of anticipating at the beginning of a search the variants which may be substituted for particular words by different authors. Such is the enthusiasm of the Chemical Abstracts Service for machine retrieval that it is presumably only a matter of time before the word guides themselves are incorporated into the machine programmes. In the meantime, etymologists will be glad to see that the word guides take a stern line on a great many malpractices. Thus those who would use the word "level" instead of "concentration" will get no encouragement from the first editions, at least.

## British Abortion Law

MR. DAVID STEEL's Medical Termination of Pregnancy Bill, 1966, which reached the committee stage of the House of Commons this week, seems assured of getting through the House in one form or another. The Bill is not quite as radical as some of its opponents (and, indeed, some of its supporters) have maintained. It does, however, extend somewhat the grounds for abortion that are already recognized in case law. It would legalize abortion if, in the opinion of two

doctors, the pregnancy endangers the life, health or well-being, whether physical or mental, of a pregnant woman, taking account of the patient's total environment. Other grounds for abortion in the Bill are substantial risk of deformity in the child, severe overstrain of the pregnant woman's capacity as a mother, and her mental deficiency, or pregnancy as a result of rape.

A number of medical organizations raised various doubts about the Bill in its original form. The British Medical Association objected to the use of the word "serious" to qualify the risk to life and of "grave" qualifying the injury to health in the original form of the Bill. Both these words could provide lawyers with talking points and lead to unforeseen interpretations. These objections were accepted by the sponsors of the Bill, who also inserted the phrase "account may be taken of the patient's total environment, actual or reasonably foreseeable". The BMA also wanted to alter some of the clauses relating to the method of notification of abortions, but the sponsors of the Bill have not taken these into account as yet. Doctors themselves are not entirely happy that the Royal College of Obstetricians and Gynaecologists is pressing for abortions to be carried out only by consultant gynaecologists. The BMA does not entirely agree with the RCOG because there are parts of Britain where consultant gynaecologists are not readily available, but it does want the operation to be performed by a consultant, or a doctor of equivalent status.

Most of the concern about the present form of the Bill centres around the "doctor's dilemma" that it might introduce. It is thought in many quarters that the Bill as it stands asks doctors to decide whether or not to abort using criteria that fall outside their special competence. This is the case when they are asked to consider the woman's "capacity as a mother" apart from her life and health. In practice these clauses may prove difficult if not impossible to put into effect, and as has been pointed out the ethical, not to speak of the legal, problems that could arise might well be considerable. Other doctors think that their role is to decide on social questions as well as on purely "medical" matters, but there is clearly considerable disagreement in the profession. One obvious pitfall to avoid is that which the Swedish law on abortion has fallen into—there the process of obtaining an abortion is so wrapped up in red tape that pregnancy is frequently well advanced before a potential mother can get permission. Difficulties like these are probably unavoidable as long as decision making rests with society and not the pregnant woman.

## Ministry Magazine

As if to celebrate the bloodless take-over of the Ministry of Aviation, the Ministry of Technology has produced the first issue of a new publication. Called *New Technology*, the magazine is intended to reach a monthly circulation of 100,000, and will be sent out free to industrialists, technologists and other interested parties. Launching the new magazine, which will cost the ministry £22,000 per year, Minister of Technology Anthony Wedgwood Benn said that it was hoped to improve communications between the ministry and those on whom its work impinges. It in

no way implied a criticism of the existing technical press, he said, and they might be happy to use it as a press service. Those interested in receiving the magazine should apply to the Central Office of Information.

The minister also spoke of the need to focus the attention of the universities on to industrial problems. This could be done through the institutes of advanced technology which were being set up in the universities; the first, in machine tool technology, is at the University of Strathclyde. Another is expected to be established quite soon, but it is not yet known where it will be.

## Civil Service Promotions

THIS is the season at which the procedure in the British civil service for deciding which scientists should receive special merit promotions gets under way. Very soon, directors of establishments will be invited to recommend the names of those senior people likely to be successful candidates for special promotion. Later in the year names will be sifted by government departments and their chief scientists and by the Civil Service Commission. Eventually a short list of candidates will be interviewed by a panel under Sir Frederick Brundrett and with members from outside the civil service. Twenty or thirty people will be promoted to a higher grade on the strength of their scientific attainments and in the hope that they will continue creative work within the public service. This year this procedure is likely to be looked at with especial care because the Fulton Commission on the civil service is bound among other things to be concerned with the way in which scientists function in public life.

This special merit promotion scheme in the British civil service goes back to 1947 and is a consequence of the Barlow Report on the civil service. At that point it was recognized by the Treasury to be imprudent that scientists could be promoted only by being shouldered with the extra administrative responsibility normally associated with higher rank. Merit promotions can now be awarded to civil servants with the rank of principal scientific officer and above, and the men and women concerned are carried on the books of the establishments outside the normal complement agreed with the Treasury. In practice, those who hold special merit promotions are expected to continue actively with scientific work, and indeed the Civil Service Commission takes care to see, by means of a review every five years, that establishments do not use the device as a means of increasing the number of senior administrators on their books.

Over the past two decades, something like a score of scientific civil servants a year have been awarded special promotions. More recently, other governmental organizations not strictly within the civil service, such as the Agricultural Research Council, the Atomic Energy Authority and (now) the General Post Office, have been included in the scheme, so that the number of special promotions has increased to something like thirty a year. Surprisingly there seems to be no danger that the promotions will be institutionalized and made to seem to civil servants as automatic accolades for senior people. At least a part of the explanation is the care with which candi-

dates are sifted. The fact that outside assessors, many of them academics, help in the selection of candidates gives the system objectivity. The awarders seem also to have been fortunate in the people chosen so far, who have been acknowledged by their colleagues as outstanding research workers. For the civil service one important consequence is that the scientific establishments are able to compete on more even terms with the universities for the services of bright people.

## Ritual and Behaviour

WHEN spiders are given lysergic acid they construct webs of more than usual regularity; they become, like man in a similar situation, withdrawn from external stimuli so that their perceptive awareness is reduced, and they cease to adjust their webs to the irregularities of the surroundings. This example is used by Sir Julian Huxley in his introduction to *A Discussion on Ritualization of Behaviour in Animals and Man* (*Phil. Trans. Roy. Soc., B*, 251, 247; 1966) to illustrate the importance of perception in ritualized behaviour. Psychedelic substances, as well as schizophrenia, distort perception to the extent that contact with external objects is prevented.

Ritualization can be described broadly as the adaptive formalization of behaviour through the influence of natural selection. It seems to have occurred in animals as a means of improving signalling to other individuals; to serve as a more efficient stimulator of more efficient patterns of action in others; to reduce intra-specific damage, and to serve as sexual or social bonding mechanisms. Sexual display and threat activities act as signals to other animals, and stimulate a particular pattern of reactions. Threat can reduce damage; in some lizards threat is expressed by size-exaggeration and fighting never occurs. The antlers of deer are so constructed that fights are rarely fatal, and are so large that combatants are often deterred. Social bonding rituals include grooming, particularly in non-human primates. In fishes, too, the removal of harmful growths from one species by another benefits both. In many mammals, play is a socializing activity, for example in young monkeys, and in lions where both adults and young are involved. During the evolution of vertebrates, ritualization has tended more towards the maintenance of efficient bonding and ceremonies have become more elaborate, with individual learning playing an increasingly important role. Particularly in the primates, ritualized behaviour resembles to some extent that of humans.

## Graduates in Industry

by our Special Correspondent

A FREQUENT criticism of British industry is that it fails to attract graduates in science and technology, or to make good use of those it does attract. The Swann and Willis Jackson Reports (*Nature*, 212, 227; 1966) on scientific manpower implied that the universities are to blame for absorbing too many of their own graduates instead of dispatching them into the world with a determination to use their talents in a directly productive way. One reason is certainly the rapid expansion of the universities, which has enabled them

to find places for increasing numbers of graduates before producing a comparable increase in their own output, but another may be that industry is unable to present itself as an attractive alternative. *Nature* has recently been talking to twelve science graduates (all men) from the universities of Oxford and London with one or two years experience of industry, and asking them why they joined, and whether they regret their decision. The names were supplied by the two university appointments boards, and the companies included breweries, computer and chemical companies, and companies in the motor industry. The only proviso is that most of the companies were large.

Very few of the group questioned admitted to any regrets. "Industry is far more interesting from the inside than it looks from the outside" was a typical comment. An Oxford chemist compared the flexibility of industry with the rigidity and absence of a defined career structure in university life—"In a big company there is bound to be a job one enjoys doing", he said. None of them expressed any desire to return to academic life, although opinions of universities varied. One graduate, working for a computer company, said that he thought academic life too dedicated, but another, an Oxford graduate also in a computer firm, remarked that "university centres around fun, industry around work". In general they neither praised nor criticized university life, and seemed not to have felt the conflicting claims of industry and the universities. For some, of course, the university option was closed because their degrees were insufficiently good. Academic life, often seen as the prize awarded for a first class degree, is unlikely to be considered by those who feel, rightly or wrongly, that they are going to get a third. Industry, which cares least what degrees its recruits have, is likely to be the beneficiary; this may explain why so few seemed to have felt a conflict. Discouraged early in their university careers, people are likely to see their degree courses as a way of qualifying themselves for something else as soon as possible.

Most of those questioned believe that scientists have as good a chance of reaching the top in industry as anyone else. The widely canvassed claim that British industry discriminates against scientists found no support. While this is unsurprising from a group of industrial scientists, there is some evidence that their optimism is justified. A study carried out in north-west England by D. G. Clark of the University of Manchester Institute of Science and Technology<sup>1</sup> shows that 80 per cent of all graduates in managerial positions are scientists. There is, in fact, a broad correspondence between the proportions of graduates from different disciplines going into industry and the proportion in managerial positions, since an earlier report by P.E.P. (ref. 2) showed that at the beginning of the fifties about 78 per cent of the graduates entering industry were scientists or technologists. A more legitimate criticism might be that industry fails to employ enough graduates generally (only 35 per cent of the managers in the Manchester study were graduates). It may be that scientists are still under-represented in the boardrooms, either because the wave of scientific managers has not reached this level yet—there are more scientists among younger managers than among older—or because of the complicating factor of background. Public schools, for instance, produce fewer scientists but more managers.

Nothing in the replies given by graduates casts doubt on these findings. Most graduates thought scientists could get to the top, but as one put it, "It depends how you define the top". He added that as a scientist he preferred to be managed by scientists, even by those who were not particularly good managers. Several expressed approval of a flexible management structure, enabling research scientists to move into management or to stay in research without loss of salary if they preferred.

The graduates were also asked why they thought more scientists did not enter industry. Two factors were blamed—prejudice in the universities, and the failure of industry to do more to improve its image. None thought it would be easy for industry to correct the situation. One man, a research chemist in a chemical firm, suggested that people in universities underestimate the quality of the work done in industrial laboratories because the companies are reluctant to publish results in scientific journals. This also makes it harder for an industrial scientist to gain recognition for his work, a most important consideration. Another, working for a computer company, seemed to feel that the task of presentation was hopeless. "The only way to find out about industry is to join it", he said. If it is true that students decide long before their final year to join industry, industry might be better advised to spread its recruiting campaign rather than concentrating on the final year students. What is necessary is to reach students at the point of decision, and the assumption that this occurs in the last year of a university course may not be justified.

One point which did emerge strongly was the importance of interviews. "It's the first interview that counts", said one London graduate in the motor industry. Companies clearly make no impression by sending unimpressive personnel to conduct interviews. Appointments boards, too, have an important role to fill. Several graduates admitted that their choice of company was decided entirely by what the appointments board had said. "At the time I thought they were wrong", said one Oxford graduate, "but now I think they were right."

<sup>1</sup> Clark, D. G., *The Industrial Manager, His Background and Career Pattern* (Business Publications, London, 1966).

<sup>2</sup> Political and Economic Planning, *Graduate Employment* (George Allen and Unwin, Ltd., London, 1956).

## Helix Stability

by a Correspondent in Molecular Biology

THE fact that helical RNA is more stable than DNA, and the similar effects observed in their synthetic analogues, have been puzzling questions for some time. A substantial new study by Ts'o, Rapaport and Bollum (*Biochemistry*, **5**, 4153; 1966) presents many new data and offers a general explanation of the stability differences. Bollum's preparations of polydeoxyribonucleotides have made possible a direct comparison of their optical properties and thermal stability with those of the corresponding ribo-polymers, and the generality of the stability differences has been confirmed.

The properties of single stranded poly-dA, poly-rA, poly-dC and poly-rC have been examined. Poly-dC, by all the criteria which can be applied, shows negligible structure in solution at neutral pH, while poly-

rC is known to be substantially in a conformation involving stacking of the bases on one another. The acid forms of the two polymers (thought to be two stranded) also show differences, particularly in their pH stability: the transition to the single stranded form occurs at lower pH by 1.5 units in poly-rC, and a difference in this respect is also found in the polyadenylic acids. Again, whereas poly-rT is known to enter an ordered (most probably two stranded) conformation under the right conditions, very little structure is observed in poly-dT.

Striking differences in optical rotatory dispersion between the various single and double stranded polymers are observed. The prominent system of Cotton effects seen in neutral poly-rA in the 260–280 mμ region are all but missing in poly-dA, although at shorter wavelengths the discrepancies are less. The hypochromicities of the two polymers are moreover comparable. The acid forms also show large differences. From the theory of optical activity in interacting systems of chromophores it is possible tentatively to infer that the bases in the ribose polymer are more skewed relative to their neighbours. Ts'o *et al.* draw a similar conclusion from optical rotatory dispersion studies of the four possible base-paired complexes of ribo- and deoxyribo- poly-A and poly-T. The distortion in the ribose containing strands is attributed to hydrogen bonding between the 2'-sugar hydroxyl (missing in deoxyribose) with the 2-carbonyl group of cytosine and uracil, and the N-3 ring nitrogen of adenine, and in particular it is suggested that this is also the origin of the differences in stability. Ts'o *et al.* have collected a considerable mass of supporting evidence in favour of such a scheme, including, for example, consideration of the positions available for attack by methylating reagents in native and denatured DNA and poly-dA, and many data indicating the existence of a similar hydrogen bond in mononucleotides.

At the same time, it is important that other types of hydrogen bond have been suggested as stabilizing agencies in polyribonucleotide helices. Models of helical RNA have been reported as showing that the 2'-sugar hydroxyl group can form good hydrogen bonds either with the ether oxygen of the neighbouring ribose or with the adjacent phosphate group. Arnott *et al.* have, however, recently stressed that no intramolecular hydrogen bond from the ribose hydroxyl is compatible with the X-ray data on crystalline helical RNA. The absence of X-ray data on single stranded helices leaves the issue in some doubt but, unless there is a configurational change during the transition from the crystalline state to dilute solution, there must be some other source of stabilization of ribo- relative to deoxyribo-helices.

Recent work by Brahms and Sadron (*Nature*, **212**, 1309; 1966) advances evidence based on the behaviour of polyinosinic acid, and the aggregation of monomeric 5'-guanylic acid, that hydrogen bonding, at least in these systems, involves the ribose hydroxyl and the phosphate group. The best evidence to implicate the latter derives from the rather narrow pH range, centred on the  $pK_a$  of the secondary phosphate group, over which helical guanylic acid aggregates will form. X-ray analyses of polynucleotide structures, especially those involving single strand stacking, will be awaited with interest.

## University News:

## University College of South Wales and Monmouthshire

DR. F. A. ROBINSON, managing director of Twyford Laboratories, has been appointed to the honorary post of professorial fellow in the Department of Biochemistry. This is the first post of its type to be created within the university, and it follows the recommendations made by the Robbins Committee on Higher Education for developing co-operation between industry and the universities.

## Appointments

THE following have been appointed vice-presidents of the Royal Society for the year ending November 30, 1967: LORD FLECK, treasurer of the society and formerly chairman of Imperial Chemical Industries, Limited; SIR ASHLEY MILES, biological secretary of the society and director of the Lister Institute; PROFESSOR M. J. LIGHTHILL, physical secretary of the society and Royal Society research professor at Imperial College of Science and Technology, London; PROFESSOR H. W. THOMPSON, foreign secretary of the society and professor of chemistry in the Physical Chemistry Laboratory, Oxford; PROFESSOR G. E. BLACKMAN, Sibthorpian professor of rural economy at the University of Oxford and director of the A.R.C. Unit of Experimental Agronomy, Oxford; DR. S. G. HOOKER, technical director (aero), British Siddeley Engines, Limited; DR. R. D. KEYNES, director of the Institute of Animal Physiology, Babraham, Cambridge; DR. N. KURTI, reader in physics, Oxford.

MR. R. H. A. SKJÖLDEBRAND, technical assistant to the managing director, and project leader of the Oskarshamn Nuclear Power Group, Stockholm, has been appointed special assistant to Dr. S. Eklund, director general of the International Atomic Energy Agency.

## Announcements

THE Trustees of the Lady Tata Memorial Trust invite applications for fellowships and scholarships for research on leukaemia, in the academic year beginning October 1, 1967. Candidates with programmes of research on any aspect of malignant disease which may throw light on problems of leukaemia will be eligible for consideration, and the awards are open to suitably qualified investigators of any nationality, working either in their own institutions or in other centres abroad. Further information and forms of application can be obtained from the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London, S.W.3. Applications must be submitted before March 31.

THE U.S. Atomic Energy Commission has approved 64 educational assistance grants totalling \$517,431 to 57 colleges and universities through its Division of Nuclear Education and Training. Twenty-one grants amounting to \$109,310 are in the life sciences group, and 43 grants totalling \$408,121 are in physical sciences and engineering. The primary purpose of the awards is to assist educational institutions in their advanced science curricula.

THE Geological Society of London has made the following awards for 1967: *The Wollaston Medal* to Sir Edward Bullard; *The Lyell Medal* to Professor W. Q. Kennedy; *The Murchison Medal* to Professor T. S. Westoll; *The Bigsby Medal* to Professor F. H. T. Rhodes; *The Wollaston Fund*, an award of approximately £30, to Mr. A. H. Stride; *The Murchison Fund*, an award of approximately £30, to Mr. F. W. Dunning; a moiety of the *Lyell Fund*, amounting to approximately £10, to each of the following: Mr. G. A. Goodlet, Mr. A. C. MacL. McKinlay and Mr. D. J. Shearman.

DR. W. T. DEAN, of the British Museum (Natural History), has been awarded the silver medal of the Liverpool Geological Society, in recognition of his contributions on the

geology of the Ordovician of the Welsh Borderlands, North West England, and Montagne Noire, France.

THE U.S. Atomic Energy Commission has presented its Distinguished Service Award to the following members of its headquarters staff for their contributions to U.S. nuclear energy programmes: E. J. BLOCH, deputy general manager; D. L. CROWSON, director of the Division of Military Application; G. F. QUINN, assistant general manager for plans and production.

MR. M. W. JENSEN, manager of engineering standards and chief of the NBS Office of Weights and Measures, has been awarded the Edward B. Ross Award, presented annually by the National Bureau of Standards, U.S. Department of Commerce, for outstanding achievement in the development of standards of practice.

DR. L. M. BRANSCOMB, chief of the NBS Laboratory Astrophysics Division at the Joint Institute for Laboratory Astrophysics in Boulder, has been awarded the 1966 Samuel Wesley Stratton Award by the National Bureau of Standards, U.S. Department of Commerce. The award, which consists of a bronze plaque and a \$1,500 honorarium, was presented to Dr. Branscomb in recognition of his "outstanding contributions and sustained leadership in the field of atomic and molecular physics".

DR. HELEN S. HOGG, professor of astronomy and research associate in the University of Toronto's David Dunlap Observatory at Richmond Hill, has been awarded the Rittenhouse Silver Medal.

THE University of Liverpool has arranged a series of safety lectures to be given on Wednesdays during the Lent term, at 2.30 p.m., in the University Lecture Theatre Building. The lectures will deal with general safety principles as well as their application to specific types of laboratory.

A SYMPOSIUM on "Structural Analysis of Polymers" will be held in the University of Bradford during February 24-25. Further information can be obtained from The Registrar, University of Bradford, Bradford 7.

A SYMPOSIUM on "Modern Developments in Food Preservation" will be held at the Grimsby College of Technology during March 20-21. Further information can be obtained from Dr. B. J. Boffey, Grimsby College of Technology, Nuns Corner, Grimsby, Lincolnshire.

A SYMPOSIUM on "Nuclear Magnetic Resonance—A Design for the Future" will be held at the Hatfield College of Technology during March 1-2. Further information can be obtained from Dr. F. J. Swinbourne, Department of Chemistry and Biology, Hatfield College of Technology, Hatfield, Herts.

ERRATUM. In line 17 of the article "Variation in a Strain of Classical *Vibrio cholerae*", by K. N. Neogy and A. C. Mukherjee, in *Nature*, 212, 303 (1966), the words polymyxin (50 µg/disk) should read Polymyxin (50 U/disk).

## CORRESPONDENCE

## Stonehenge

SIR,—I have read with much interest a number of articles on Stonehenge as a possible computer. It occurs to me that it might be just possible that the circle of Aubrey Holes is a notation indicating a FORTRAN IV "DO-LOOP", the number of holes being the terminal value of the index.

Yours, etc.,

JOHN STANLEY

Professor of Population Dynamics,  
McGill University,  
Montreal 2, P.Q.

# The Stereotypical Scientist

by  
L. HUDSON

Research Centre, King's College, Cambridge

Do schoolboys regard the scientist as dull? A recent study may be relevant.

At the age of 15 or 16 most able English schoolboys face a choice between the arts and sciences. Boys who specialize in science are known to differ both intellectually and in personality from those who specialize in the arts<sup>1,2</sup>. Scientists, for example, have been found to be reticent in their expression of emotion<sup>3</sup> and to deal with personal relationships in an inhibited fashion<sup>3</sup>.

Further evidence suggests that there exist certain stereotypical beliefs about the personal characteristics of arts men and scientists. American students see the scientist as highly intelligent and masculine, but lacking in sensitivity and concern for people; as gaining satisfaction from his work, but having a shallow personal life<sup>4</sup>. Previous research on this topic, however, suffers a central weakness. It does not indicate whether such attitudes are shared by potential arts and science specialists alike.

The first part of the present enquiry was based on the "semantic differential"<sup>5</sup>. The individual rates a number of typical figures (for example, Mathematician, Poet) on pairs of adjectives (such as exciting/dull, dependable/undependable), each rating being on a seven-point scale (for example, "extremely exciting" to "extremely dull"). The sample ( $n=390$ ) was limited to 13, 15 and 17 year old boys of high academic ability, drawn from two schools, one public boarding and one grammar.

The present data confirm the American result. The typical physical scientist emerges as entirely distinct from typical figures in the verbal arts. Table 1 shows one contrast, representative of the data as a whole: that between the Physicist and the Novelist (of twenty mean ratings given, eighteen are statistically significant:  $P<0.05$ ). The semantic differential also includes a number of typical women and, again, American findings are borne out. Compared, for example, with the wife of the Novelist, Doctor or Barrister, the wife of the Research Scientist is seen as dull and plain.

The sample was then broken down by academic speciality, and two sub-groups formed: (i) arts specialists, taking a sixth form course in English, history or modern languages ( $n=75$ ), and (ii) physical science specialists, studying mathematics, physics and chemistry ( $n=67$ ). Their responses were then compared.

Fig. 1 shows the contrast between Novelist and Physicist, as seen by arts specialists and by young physical scientists. Despite "haloes" of approval for members of their own speciality, the attitudes of the two groups are strikingly similar. Both groups agree that the Novelist is the more imaginative, warm and exciting; the Physicist the more dependable, hard and hard-working. (Of differences plotted, nineteen deviate significantly from

Fig. 1. Differences between "the Novelist" and "the Physicist", as seen by young arts specialists ( $n=75$ ) and by young physical scientists ( $n=67$ ). Each point represents a difference between two mean ratings on the semantic differential—one for "Novelist", the other for "Physicist". Differences are converted to a scale from zero to 1.00.

Table 1. QUALITIES ATTRIBUTED BY SCHOOLBOYS ( $n=390$ ) TO TWO FIGURES: "THE NOVELIST" AND "THE PHYSICIST"

Novelist		Physicist	
Imaginative	0.86	Valuable	0.72
Warm	0.48	Intelligent	0.58
Intelligent	0.41	Hard-working	0.51
Exciting	0.38	Dull	0.32
Valuable	0.31	Dependable	0.31
Undependable	0.30	Cold	0.29
Smooth	0.19	Hard	0.28
Soft	0.19	Manly	0.27
Feminine	0.12	Rough	0.13
Lazy	0.04	Unimaginative	0.03

Mean ratings on the semantic differential converted to a scale from zero to 1.00, where zero represents the absence of a given quality, and 1.00 the maximum possible rating upon it.

zero:  $P < 0.05$ ). Furthermore, the two groups agree closely in their rank ordering of discriminative adjectives from "warm" to "dependable" for the arts group, and from "imaginative" to "dependable" for the young scientists:  $r_s = 0.88$ ,  $P < 0.01$ .

Analogous results emerge from the contrast between the wife of the Novelist and the wife of the Research Scientist. Both groups agree that, of the two, the wife of the Novelist is significantly the more exciting, feminine, soft, imaginative; while the wife of the Research Scientist is the more dependable. (In each case,  $P < 0.05$ .) Agreement in the rank ordering of adjectives is again high:  $r_s = 0.91$ ,  $P < 0.01$ . Substantially, the relations shown in Fig. 1 hold true for boys of all academic specialties, and for all typical figures relevant to the arts/science choice. Furthermore, such stereotyped attitudes are found as pronounced among unspecialized 13 year olds as among specialists of 17.

A clear implication of these data is that adult scientists are seen by both future arts and science specialists as leading dull personal lives. It was to explore this particular inference that a "typical graduates questionnaire" was devised. A typical male arts graduate and a typical male science graduate are compared in the light of thirty characteristics, some general (such as "competitive with others") and others specific (such as "wears fashionable clothes"). Responses are on a five-point scale, ranging from "arts graduate much more likely" to "science graduate much more likely". The sample used was of similar composition to the first. Each item in the questionnaire yielding a significant rating for both arts and science specialists is given in Table 2 ( $P < 0.05$ ). These results suggest that both groups see the typical arts graduate as the more pleasure-seeking and irresponsible figure, and the typical science graduate as the more puritanical. The agreement between the rank ordering of items is again high: for all thirty items,  $r_s = 0.82$ ,  $P < 0.01$ .

It might be protested that such evidence is trivial: arts and science specialists may differ in the value they

Table 2. COMPARISON OF QUALITIES ATTRIBUTED TO THE "TYPICAL ARTS GRADUATE" AND THE "TYPICAL SCIENCE GRADUATE" BY YOUNG ARTS SPECIALISTS ( $n=79$ ) AND BY YOUNG PHYSICAL SCIENTISTS ( $n=59$ )

Young arts specialists' view			Young physical scientists' view		
Arts	Wears fashionable clothes	0.62	Wears fashionable clothes	0.57	
Graduate	Sociable	0.61	Gets divorced	0.39	
>	Likes wife to look		Panics in emergencies	0.39	
Science	glamorous	0.52	Flirts with his secretary	0.38	
Graduate	Flirts with his secretary	0.51	Sociable	0.34	
	Gambles	0.49	Gets into debt	0.30	
	Likes expensive restaurants	0.42	Gambles	0.28	
	Gets into debt	0.36	Likes expensive restaurants	0.25	
	Gets divorced	0.30	Likes wife to look		
	Has fast car	0.23	glamorous	0.23	
	Panics in emergencies	0.18			
Science	Faithful to wife	0.19	Embarrassed (for example,		
Graduate	Embarrassed (for example,		about sex)	0.18	
>	about sex)	0.24	Has fast car	0.23	
Arts	Competitive at work	0.25	Faithful to wife	0.31	
Graduate	Works long hours	0.58	Competitive at work	0.43	
			Works long hours	0.70	

Mean ratings on the "typical graduates questionnaire" converted to a scale from zero to 1.00, where zero represents the absence of a given quality and 1.00 the maximum possible rating upon it.

attach to such adjectives as "warm" and "cold". Further evidence from the semantic differential refutes this. Arts and science specialists agree overwhelmingly in attributing the adjectives intelligent, imaginative, exciting, warm, dependable and valuable to figures defined in the test as "good" (for example, Good Father, Good Teacher, Good Friend).

It seems, in summary, that whatever their speciality, the attitudes of boys towards the arts and sciences are influenced by a common set of preconceptions. Psychologically, this finding is intriguing. Large numbers of boys choose careers in the physical sciences, believing as they do so that the personal life of the adult scientist is unexciting. This choice may represent a reluctant compromise, but previous research suggests that it will frequently be made gladly, and even with a sense of relief<sup>2</sup>. Such stereotyped preconceptions may also help to explain why, contrary to predictions of a historical or economic nature, the proportion of able children recruited to the physical sciences in Great Britain has failed to increase since 1960 and may indeed have decreased<sup>3</sup>. It remains unclear, however, where boys' stereotyped ideas originate and to what extent they are open to change.

These results arise from a programme of research supported by the Nuffield Foundation.

# Marion and Prince Edward Islands

Early in January 1965 a scientific expedition to the isolated Marion Island and its small companion Prince Edward Island in the Southern Ocean was launched by the Republic of South Africa. The following article is a preliminary report of the early investigations undertaken of the biology and geology of the two islands.

## Biological Studies

A CONCERTED effort has been made to study the animal and plant life of the two small sub-antarctic islands, Marion and Prince Edward, which are situated at 46° S. In their geographical position these islands can be compared with Crozet and Kerguelen Islands. An expedition was sponsored by the South African Government under the supervision of the South African Council for Scientific and Industrial Research and consisted of four biologists and two geologists.

The party stayed on Marion Island from January 4 until March 17, 1965, and on Prince Edward Island from March 18 to 22, 1965. Two members, B. J. Huntley and E. M. van Zinderen Bakker, jun., then returned to Marion Island for a further stay of 12 months, while the others left for Cape Town on the research ship the *R.S.A.*

After arrival the biological team organized a field laboratory which was provided with apparatus for research in ecology, cytotaxonomy, palynology, pedology, hydrobiology and for general collecting activities. Electric power was available for this work and an existing small greenhouse proved to be very suitable for experimental work.

## Systematics and Endemism

The first aim of the expedition was to make representative collections of all the taxa which are to be found on the island and in the intertidal zone. A number of specialists have consented to investigate the material. The flora and fauna, especially those of Marion Island, should be well known when this work is completed. Special attention was directed to endemism and the problem of long distance dispersal in connexion with the isolated position of the islands. The list of the limited number of flowering plants has so far been extended with two species of *Juncus* and one of *Limosella*. An extensive investigation of the chromosome patterns of the flowering plants and ferns was carried out in order to obtain information about the populations of plants which occur. Special attention was also directed to problems of the speciation of certain groups of animals, such as the wingless butterfly *Pringleophaga*, wingless flies, fresh water Crustacea, Curculionidae and others of which interesting material had been collected.

The systematic and biogeographic investigations cover, besides the two plants already mentioned, the Musci, Hepaticae, Lichens, macroscopic fungi, and the fresh-water and marine algae. A great variety of lower invertebrates were collected with the aid of Berlese funnels and nets and also by squeezing sap from plant material.

In the intertidal zone about 250 different animals were collected together with 200 samples of marine algae. A 'Neoprene' 'wet-suit' was used for diving, which enabled the marine biologist to stay in the water for up to an hour at a time. Fish and plankton were regularly collected.

The ornithological programme was directed by Professor J. M. Winterbottom, director of the Percy Fitzpatrick Institute of African Ornithology at the University of Cape Town. By early 1966 twenty-four species of birds had been observed. An extensive study was made of the distribution of the birds, especially of the large

numbers of rockhoppers, Gentoo, Macaroni and King penguins, in the rookeries.

## Ecology

The ecological research was concentrated on different fields. The botanist studied the plant communities and their micro-climate with the aid of a battery-operated six-point temperature recorder. These investigations revealed interesting differences between the habitats and especially the degree of protection provided by the cushion growth form which is so common on the islands. The study of the great influence of seals, penguins, night birds, gulls and the extensive rookeries on the vegetation may provide an explanation for the vegetation pattern and succession in the coastal region.

Special attention was paid to the extensive swamps which occur on the island and which develop in an oligotrophic direction. The peat contains well preserved pollen, and some borings, which were made on a reconnaissance expedition to Marion Island in 1963, revealed an age of about 5,000 years for some of these swamps. More borings were made this time and recent pollen material has been collected. At a later stage borings will be made on Prince Edward Island.

The ornithological programme paid special attention to the aetiology of the sooty albatross and the Gentoo penguin, both of which occurred in fairly large numbers near the expedition's base. A 16 mm cine film was made to show the behaviour of these birds and the temperature recorder was used for studies of their breeding habits. The population dynamics of the royal albatrosses was also studied, as these birds occur in large numbers on the islands. An extensive banding programme, for which bands of the U.S. Antarctic Research Program were used, was undertaken. Special attention was also paid to the night birds and protein samples were collected for serological work.

The ecology of the intertidal flora and fauna was studied at five different stations situated at various points around Marion Island and at two stations on Prince Edward Island. The transect method was used. Temperature and chemical determinations were regularly made and some experiments on lethal temperatures were conducted with molluscs.

After much experience had been gained on Marion Island, the short stay on Prince Edward was extremely important, as the latter island is inhabited mainly by the same species, but very interesting differences exist in the flora and fauna, and especially in the general ecology and the age of these two islands. From the biological point of view it is estimated that Prince Edward is the older of the two with a more advanced drainage system and consequently a different ecology.

**Patterned soil.** Some interesting types of polygons and stone lines were discovered on both islands and will be studied in detail. The temperature recorder was used on these sites to assess the microclimate which is responsible for these freezing-thawing effects.

**Conservation.** The conservation of the ecosystems of the islands and of their flora and fauna was an important consideration in the scientific programme. The South African Department of Transport, which is responsible

for the permanent Weather Station of Marion Island, is interested in the preservation of the wild life of the island and will see that the disturbance of the vulnerable flora and fauna will be as small as possible. So far eight different weeds have been found on Marion Island. The vegetation on Prince Edward is practically undisturbed.

The results of this expedition are being worked out in co-operation with colleagues working on similar islands and in contact with the U.K. Scientific Committee on Antarctic Research. It is intended to publish the records of the expedition in the form of a monograph.

E. M. VAN ZINDEREN BAKKER

University of the Orange Free State,  
Bloemfontein, South Africa.

## Geological Studies

A BRIEF note<sup>1</sup>, emphasizing the lack of geological knowledge about Marion and Prince Edward Islands, appeared in *Nature* two days before we set foot on the larger island in order to commence its first systematic geological survey. The field work, which entailed topographic and geological mapping, volcanological observations and sampling for geochemical, petrographical, geochronological and palaeomagnetic purposes, was completed between January and March 1965. This included a 5 day visit to Prince Edward Island of which no reliable map or any scientific information has yet been published. The generalized geological

maps presented here (Figs. 1 and 2) are based on triangulation, Royal Air Force air photographs corrected by radial line plotting, and field sketches. Petrographic and other investigations are still in progress and will eventually be published in the final report of the expedition.

## Marion Island

Marion is a sub-antarctic island situated about 900 nautical miles south-east of Cape Town (lat.  $46^{\circ} 54' S.$ , long.  $37^{\circ} 45' E.$ ). It is near the junction between the Atlantic-Indian and Crozet Ridges, occupying a similar position with respect to sub-oceanic ridges as the Tristan da Cunha island group much farther west. The island represents the top of a volcanic cone rising steeply from the ocean floor at a depth of about 12,000 ft., but has a low dome-like profile above sea level. There is no central cone or crater, and no evidence of previously existing ones. The summit, Jan Smuts Peak (alt. 3,890 ft.), is one of numerous scoria cones dotted about the island.

The island is roughly oval in outline and is some 115 square miles. It measures 15 miles from east to west and 10.5 miles from north to south. The western half is exposed to strong westerly trade winds often reaching gale force. Above 1,000 ft., this area is shrouded in almost perpetual cloud while the summit area from Jan Smuts Peak westwards carries a permanent or semi-permanent snow cover.

Physiographically the island can be divided into (a) a coastal plain, (b) an inland slope, and (c) the summit plateau.

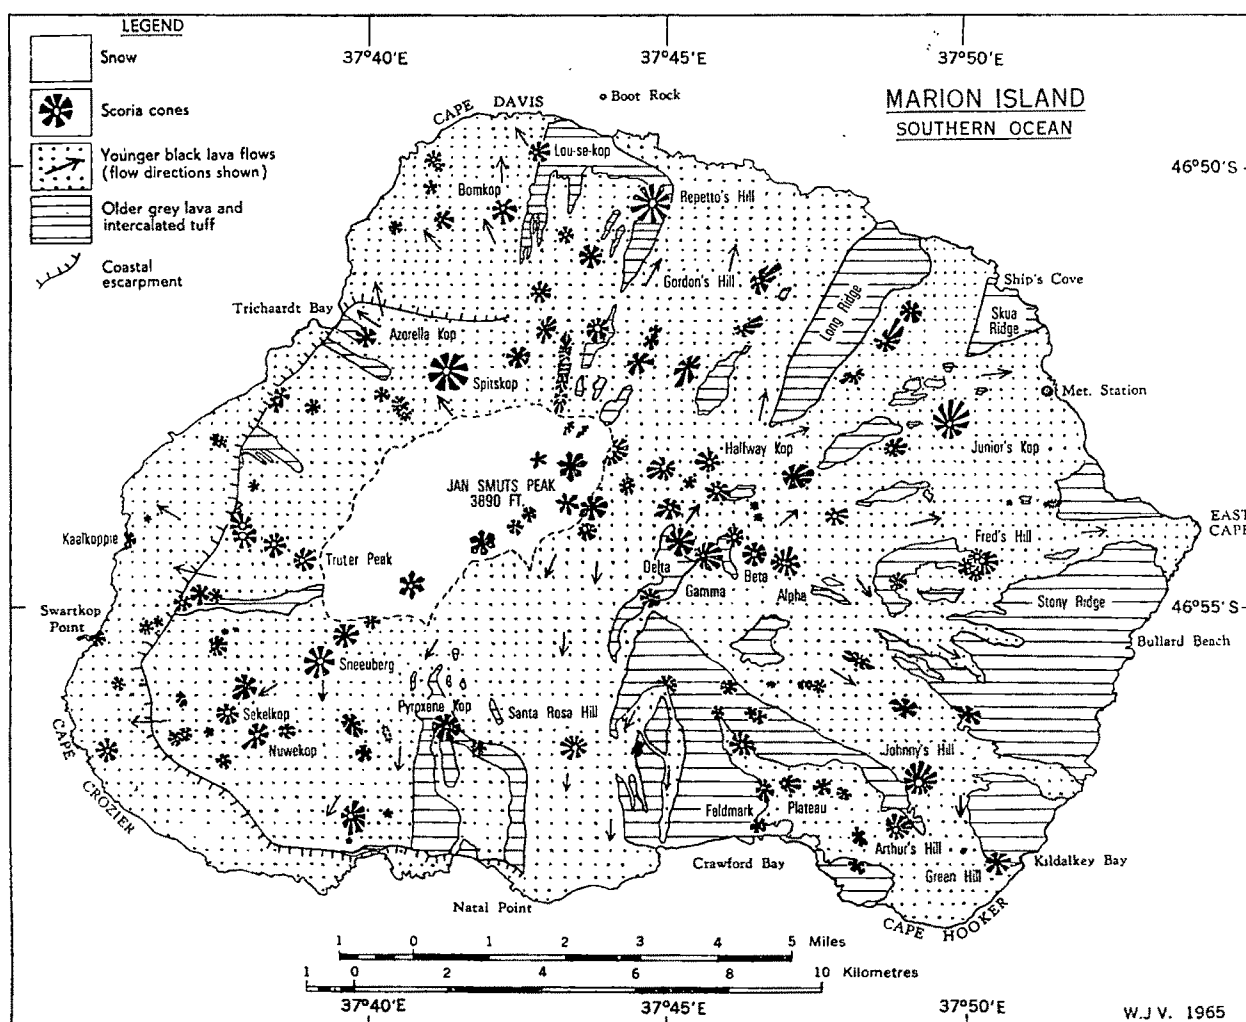

Fig. 1.

The coastal plain is only present along the western and south-western periphery of the island. It varies in width from 0.5 to 1.5 miles, and has an average altitude of 120 ft. above mean sea level. The generally flat, marshy surface is diversified by a few younger cones and lava flows. It is separated from the inland slope by an escarpment, 600–1,200 ft. high, trending parallel to the coast. Although the escarpment obviously represents a former coastline, the coastal plain is not considered to be a raised wave-cut terrace. It is built of lava that flowed over the escarpment on to an eroded shelf which is still submerged. The entire coastline of Marion combines the characteristics of retreat due to marine erosion and advance by seaward flow of lava. Low-lying areas which can perhaps be regarded as portions of a coastal plain are also found in the north-eastern half of the island, for example, between Repetto's Hill and Long Ridge and at East Cape. These areas, however, have tectonic boundaries and merge gradually with the inland slope; they are therefore different from the south-western coastal plain, both in shape and origin.

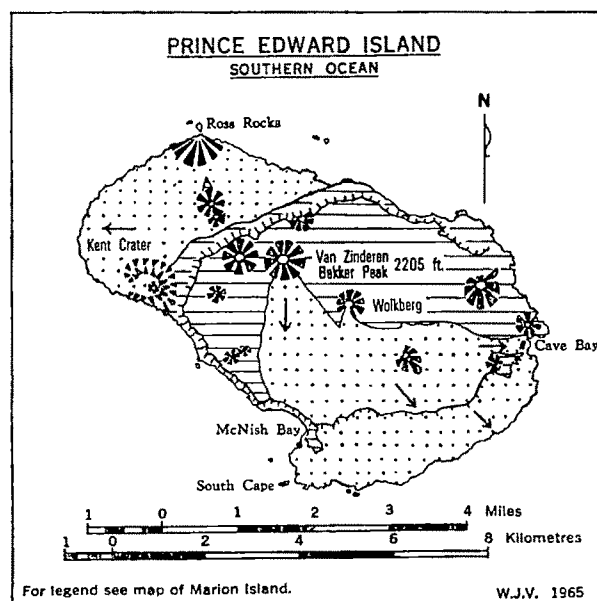

Fig. 2.

The inland slope comprises the greater part of the island. Despite a fairly smooth profile, the slope is by no means an even surface. Conical hills rise up to 750 ft. above it, and the eastern half of the island consists of roughly triangular plains and plateaux arranged around the central peaks in alternating fashion. Long Ridge and Feldmark Plateau are two of the most prominent highlands, adjoined on both sides by broad valleys that can be ascribed to relative depression. Stony Ridge is part of a segment with intermediate elevation.

The summit plateau is a narrow strip above 2,500 ft. extending for a distance of about 4 miles from Alpha Kop westwards. Two conspicuous cone lines, one from the south-west and the other from the south-east, meet here. Vast quantities of younger black lava were poured out from the summit plateau on to the lower slopes.

Geologically, two stages in the evolution of the island can be distinguished. The first stage is represented by a succession of grey lava flows (trachybasalt?) with interbedded tuff and agglomerate. The lava flows dip at low angles seaward and vary in thickness from a few to about 100 ft. They are vesicular but very seldom scoriaeous. Most grey lava is massive and often it is columnar jointed. Megascopically, several petrographic types appear to be present, some of them porphyritic. Gabbroic

or ultrabasic inclusions have not been encountered. The areas built of the grey lava succession strongly contrast with the younger black flows and protrude as isolated inliers through the latter. The grey succession is thought to be much older because its topography is smoothly rounded, well established water courses exist, minor irregularities of the coastline have been erased, and prolonged mechanical weathering has resulted in surfaces strewn with rock slabs.

The second stage again gave rise to effusive and pyroclastic products, the latter being restricted to the mostly unconsolidated cone-building scoriae already mentioned. The lava belonging to this stage is black basalt with olivine but individual flows contain different proportions of feldspar, olivine and pyroxene phenocrysts. The two analysed specimens described by Abbott<sup>2</sup> undoubtedly belong to the younger suite, even though he referred one of them to the older grey series. The numerous flows that must have succeeded each other over a long period of time can be distinguished. Some are covered with vegetation on the lower slopes of the island, while others are bare and appear to be no more than a few hundred years old. Some scoria cones are partially buried by the latest lava flows. The most striking difference between the black lavas of the second stage and the older grey succession is that the former still shows all the primary features of an uneroded volcanic landscape, for example, lava tunnels, lava channels, lava levees, tumuli, spatter cones, craters, aa and pahoehoe. The stream pattern is determined by the contacts between adjacent flows, while the previously established drainage has been disrupted at many places by black lava flows following pre-existing valleys. Where outbuilding flows of black lava form the coastline, initial irregularities have been accentuated by wave erosion.

There is considerable evidence in favour of tectonic movement between the two stages. The high plateaux are invariably built of older grey lava and intercalated tuff, to a greater or lesser extent concealed by younger lava flows. In the intervening plains and valleys, however, the grey succession is buried beneath great thicknesses of younger black lava. The plateaux are often bounded by straight lines of cliffs extending radially from the central highland. Moreover, some scoria mounds are also aligned along such radii. It is concluded that the major features of the inland slope are fault blocks; the valley containing Santa Rosa Hill, for example, is best described as a rift valley. Variable tilting of individual blocks during radial fracturing would also explain, in part, the asymmetric development of a coastal escarpment.

We found no fumaroles or other signs of recent volcanic activity.

### Prince Edward Island

Prince Edward Island is 12 nautical miles north-north-east of Marion and represents a subsidiary peak of the same volcano. Two stages in the geological evolution corresponding to those on Marion have been recognized. The older group of grey lava and tuff builds mainly the central, high part of the island bounded on the north-west and south-west by steep coastal escarpments, up to 1,500 ft. high. During the second stage of volcanism, scoria cones were built up on the older succession and black basaltic flows extended the island both to the north-west and south-east. The black lava flows are all covered with vegetation, which seems to suggest that volcanic activity on Prince Edward came to an end earlier than on Marion.

## BOOK REVIEWS

## BEAU TEMPS

Les écrivains français et la météorologie de l'âge classique à nos jours

By L. Dufour. Pp. 122. (Bruxelles: Institut Royal Météorologique de Belgique, 1966.) n.p.

METEOROLOGY has been called by some the physics of the atmosphere and by others the science of the weather. As soon as we bring in that splendid word, with its Norse affinities, we are conscious of a subject that touches our emotions; something we have to live with. Earlier French poets, like the British, were thrilled by the simple emotions of springtime; Charles d'Orleans was writing his rondeaux when William Langland was enjoying his May mornings. Sixteenth-century Caliban's instinctive knowledge led him to roar: "All the infections that the sun sucks up on Prosper fall". Attitudes change; four centuries later, the meteorologist prefers to examine the extent to which limited convection can develop in the lower layers of the essentially stable atmosphere surrounding a small island in early summer, bearing particulate matter for but a short distance. From the seventeenth century onward, literary expression has seen the rise of logical prose at the expense of emotional poetry; but within this frame, the literature of Western Europe has continued to abound in expressions of those responses that the variable westerly weather that we all share continues to provoke.

It is entertaining to find a work such as this appearing from an official meteorological service, but, after all, meteorology and Molière came in together. M. Dufour is a doctor of science whose agreeable purpose is to discuss one aspect of the relationships between science and literature. He concludes by suggesting that the authors who have best described the phenomena of the atmosphere are not the scientists, but those who have been moved to do so by physiological, aesthetic or other considerations. Here he begs the question. What, after all, is satisfactory description? Can feelings be adequately conveyed in the words of a scientist to anyone other than a scientist?

M. Dufour has much to say about Bernardin de Saint Pierre and his imaginative descriptions of the weather at sea, no doubt influenced by accounts of the voyage of Bougainville. We can counter with Coleridge and Cook. He finds the first lively comments on French weather in the letters of Mme. de Sévigné; we have to seek Evelyn's diary, or wait for Horace Walpole's prolific output. Early in the nineteenth century Chateaubriand reveals a lively regard for the weather at a very proper period, when Gay-Lussac was ballooning above Luke Howard's clouds. Dorothy Wordsworth and Stendhal displayed their sensitiveness to the moods of the weather at very much the same time; and perhaps we might offer Meredith as a counter to Victor Hugo. We are brought down to the descriptions of Saint Exupéry, who was an air pilot before he took to writing.

Thoughtful scientists who like to observe the phenomenon of literature, as well as liking it, will find the author's comments and extracts interesting, for France and England have shared many fashions in common. Meteorologists will see in them that background of regard for the weather that the countries of Western Europe must share; even as the "ciel lumineuse" of the Ile de France, the clear light of East Anglia and the grand mobile skies of Holland towards the edge of the prevailing track of Atlantic

depressions have enlivened their painters. Englishmen can reflect on how long they have continued to express so much of their feeling in poetry. Is this because too many Frenchmen have been led to seek the town, while we still battle to keep our hold on the land, our little patch of suburban garden in Surrey or Cheshire where the west wind can still be felt?

GORDON MANLEY

## PROBABILITY OR SUPPORT?

Logic of Statistical Inference

By Ian Hacking. Pp. ix+232. (London: Cambridge University Press, 1965.) 40s. net; \$7.50.

THIS book is a philosophical discussion of statistical inference, better informed than most others on the subject by professional philosophers, and written in a lively and provocative style.

The book is based on a notion close to that of subjective probability but which the author calls "support", by analogy with Carnap's equally misleading use of the word "confirmation". He says (page 221) that he has not defined "support" but has used it in its familiar English usage. He does sometimes, and the double meaning leads him to deny himself one of the axioms of (partially ordered) intuitive probability. Therefore, as he says (page 208), his theory cannot reach as far as existing theories of (either logical or) subjective probability. He cites (pages 32-33) some axioms of intuitive probability due to Koopman, calls them "axioms of support", and says they are indispensable to the rest of the work, but cites one of them incorrectly (as he has since noticed). The argument at the foot of page 33, in which he disputes one of Koopman's axioms, is wrong when the axioms are concerned with intuitive probability, as Koopman intended them to be.

On page 41 Nelson Goodman's riddle is said to "combine precision of statement, generality of application, and difficulty of solution to a degree greater than any other philosophical problem broached in this century". The riddle is: "Let 'blight' mean 'black until the end of 1984 and white thereafter', . . . Goodman argues that every shred of evidence which supports the claim that most balls in an urn are black . . . equally supports the claim that most are blight . . .". The reviewer thinks that, from the point of view of subjective probability, there is no riddle: the initial probability of blight is very much less than that of "black" and, therefore, so is its final probability. A riddle does arise if "support" in the sense of probability is confused with its English meaning, best explicated by "weight of evidence", defined as  $\log \{O(H|E)/O(H)\}$ , where  $O$  denotes "odds",  $H$  a hypothesis, and  $E$  an experimental result, evidence, or event.

In the discussion of fiducial probability the author tries to salvage something from Fisher's fallacious arguments. I find the discussion obscure here, but, as far as I can understand it, it seems to me to depend on an assumption (page 141) that relative support is proportional to relative likelihood. Since the author's interpretation of "support" is also that of  $P(H|E)$ , this assumption is essentially the same as a principle of indifference, in spite of protestations (page 207) to the contrary.

From the standpoint of the sociology of philosophy it is interesting that so many philosophers should have been misled by the misuse of the single word "confirmation"—albeit by a famous philosopher. The author, in spite of his undoubted intelligence, is among these, although, to distinguish his work from that of Carnap, he uses the word "support". Inherently lucid in style, he is driven into complications and obscurities in his attempt to defend a position that is basically untenable. "If the first button is buttoned wrongly, the whole vest sits askew."

Although he starts on the wrong foot or button, there are many stimulating passages, and even some opinions

which I have often supported. For example (page 32), the importance of partial ordering of intuitive probabilities is emphasized: and (on pages 212–213) Hacking expresses simultaneous admiration and dissatisfaction with de Finetti's explanation of physical probabilities in terms of subjective probabilities. He has privately apologized for misrepresenting me on page 110. I. J. GOOD

## PLANNING AHEAD

### Manpower Planning

Operational Research and Personnel Research. (A Conference under the aegis of the NATO Science Committee, Brussels, 17–20 August 1965.) Pp. v+291. (London: English Universities Press, Ltd., 1966.) 55s. net.

THERE is much of interest to manpower planners, at the level both of the company and of the national economy, in this volume of conference papers. The authors describe a part of the military experience of a number of member countries of NATO in dealing with problems of recruitment, training and the efficient use of human resources. It is not for the first time that war—or the preparation for war—has meant that a particular management problem has been taken seriously; and it is not surprising that a quarter of the conference papers should be concerned with the operational research techniques themselves, rather than with the subject matter to which they might be applied.

Two of the discussions at the conference centre round the human element in personnel planning. The selection of an individual for employment, or enlistment, often occurs before any judgment can be made about the successful fitting of man to job. No personnel or recruiting officer can avoid applying tests, whether objective or subjective, at the interview. Co-operative investigation by psychologists and operational researchers should in the future indicate the attributes of human personality which ought to be tested and the criteria that should be used for later performance—questions to which, at the moment, only partial answers may be possible.

The training of the individual to a pitch of proficiency required by the job is the second subject discussed. This is something to which military manpower planners apply quantitative techniques, and it is from this subject that programmed learning stems. For those to whom the idea of such a technology of training is still novel, there is a detailed and fascinating comparison in cybernetic terms between a closed loop system (in which the performance of the trainee feeds back to determine the training stimulus) and the open loop system characteristic of conventional training courses. Training officers in industry could well take note, if they have not done so already, of the principles that emerge from this idea: rigorous job analysis, specific objectives to any training course, a variable training period and a fixed end-result (rather than fixed training period and variable end-result).

The employment of human resources, considered as a group rather than as individuals, poses two types of problems for the manpower planner, one of which is discussed explicitly. This is the natural or induced rates of participation in a certain form of employment, in this case membership of the armed forces; and the geographical and hierarchical mobility required or made possible by the strategic location and command system of the armed forces. Solutions to the analogous industrial problems are suggested here: the industrial labour market may, for example, yield similar measurable supply curves which indicate pay-setting procedures effective in obtaining adequate labour.

The conference was almost entirely silent on the other main problem of manpower planning, though there were signs that it had not been neglected. This is the estimation of future needs for various types of men. The in-

redients for a solution must be: future military budgets, the technology of future weapon systems, and the needs that these imply for servicemen of different ranks and skills. Clearly a considerable integration of the personnel and technological planning activities takes place—you do not design a warship without detailing its crew's accommodation or an electronic tracking system without its maintenance staff—and this consideration greatly simplifies the problem of forecasting the manpower needs of future techniques in a military context. The need for military secrecy may hide the details of how such tasks are carried out, but the lesson for civil manpower planners is the need to co-ordinate economic, technological and manpower information relating to the future.

Finally, it should be said that the price of this volume seems excessive. It is adequately but by no means elegantly produced, being in fact offset reproduction from unjustified typescript. It is a conference volume, and so it seems likely that royalty considerations would not loom very large. And it is sponsored by an international organization which, in organizing conferences, must be mainly concerned with the exchange and dissemination of ideas.

RICHARD STONE

## BODY FLUID CONTROL

### Electrolytes, Fluid Dynamics and the Nervous System

By Joseph Henry Cort. Pp. 228+3 plates. (Prague: Publishing House of the Czechoslovak Academy of Sciences; New York and London: Academic Press, 1965.) \$10.

THIS is an unusual book on fluid and electrolyte metabolism. The chemical structure and routine analysis of the body fluids are not dealt with—no matter as there are many excellent texts available—but what is unique is the comprehensive and detailed consideration of the control of the fluids and electrolytes of the body and especially mechanisms which may be involved in the control of extracellular fluid volume. The important chapters are Chapter 3, "A Selective Review of Those Parts of the Nervous System thought to be involved in the Regulation of Body Fluids" (eighteen pages); Chapter 4, "The Innervation of Separate Organs in relation to Their Interactions with the Extracellular Fluid" (thirty-one pages); and Chapter 7, "'Volume' Reflexes, or the Relationship of Haemodynamics to Na Balance" (seventy-nine pages).

One of the crucial observations considered in Chapter 7 is the rise in water and sodium excretion which occurs when both common carotid arteries are occluded. Cort believes that this natriuresis depends partly on afferent impulses arising in the thorax, as the response is reduced after cervical vagotomy. The fact that vagotomy also augments the pressor response to carotid occlusion makes it unlikely that it is the rise in filtration pressure which causes natriuresis. Furthermore, the posterior nucleus of the hypothalamus appears to be involved in processing the afferent nerve impulses from the various baroreceptors, because after destruction of this region an animal goes into negative sodium balance and the natriuretic response to carotid occlusion is abolished. The onset of the natriuretic reflex is rapid and the reflex can be elicited after adrenalectomy; it can also be obtained during infusion of aldosterone, vasopressin or angiotensin in amounts which are large compared with the amounts produced endogenously; finally, denervation of the kidneys or administration of dibenzylamine does not seriously affect the response. Thus the efferent signal to the kidney is probably humoral, though neither aldosterone, vasopressin, angiotensin nor the catechol amines are involved. As a working hypothesis Cort suggests that the natriuretic response involves "1. inhibition of release of an anti-natriuretic factor (? vasotocin) related to inhibition of

posterior hypothalamic activity and 2. release of an oxytocin-like peptide or its precursor". In all this he does not understate the possible importance of aldosterone in the long term regulation of extracellular fluid volume.

Rather less satisfactory is the treatment of acid base balance and osmoregulation, mainly because these sections are so brief, but also because some of the statements made are open to question. It is not accurate to say that the anti-diuretic hormone osmoreceptors normally respond to rate of change of osmolality rather than the absolute level: Verney showed twenty or more years ago that these receptors do not adapt when exposed to sustained small increases in osmotic pressure. Osmoreceptors may give transient responses, but these would not be particularly helpful in the long term regulation of osmotic pressure where some sort of proportional control is required.

Cort is deliberately polemical, for he believes that an unopinionated book seldom makes good reading, and I think many would agree with him. Running through the text is the argument that in classical physiology we usually study an isolated mechanism under rigidly defined conditions and often under anaesthesia. We quite naturally interpret the behaviour of the intact conscious animal in terms of this mechanism, often without taking into account the possibility that there are other unknown and perhaps more important mechanisms which may supplant and certainly modify the original mechanism. Several completely different types of mechanism may function in parallel towards the control of some important variable the stability of which is essential for life. As examples of this we may note that the adrenalectomized rat will maintain reasonable health and sodium balance if provided with saline to drink, and that the serum osmotic pressure in diabetes insipidus is close to normal despite the greatly increased turnover of water. Even in experiments in which we are apparently at pains to study the responses of an animal with all its mechanisms functioning, as in balance studies, we may be deluding ourselves because the animal is usually placed on a constant intake while the renal regulation of some variable such as osmolality or volume is studied. We must remember that the central nervous system plays a part in both sides of the balance equation, that there is often a change in voluntary intake to a given stress as well as a renal response and that intake and excretion normally interact and modify each other. Cort asks the somewhat enigmatic question "... is the whole, working, biological system a sum of its parts, i.e. mechanisms, or does it represent a qualitative quantum jump over the individual regulating mechanisms?"

In short, this is a most stimulating book that covers every aspect of the control of body fluids. It is easy to disagree with many of the ideas that are advanced, but they are put forward with the intention of arousing interest, which they do, and of provoking research, which they will.

J. T. FRIZSIMONS

## BETA DECAY IN REVIEW

### The Theory of Beta Radioactivity

By E. J. Konopinski. (The International Series of Monographs on Physics.) Pp. x+403. (Oxford: Clarendon Press; London: Oxford University Press, 1966.) 75s. net.

### Beta Decay

By C. S. Wu and S. A. Moszkowski. (Interscience Monographs and Texts in Physics and Astronomy, Vol. 16.) Pp. xiv+394. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1966.) 120s.

THE story of the development of the theory of  $\beta$  decay and from this of the theory of weak interactions in general

is one of the most fascinating in physics. It began with a puzzle, the continuous  $\beta$  spectrum, solved by Pauli by the introduction of the neutrino in 1931. Then, after a period of gradual progress initiated by Fermi in 1933, came that extraordinary *volte face* in 1956, the breakdown of parity conservation. This was first proposed by Lee and Yang and subsequently verified experimentally by Miss Wu and her collaborators in 1957. At once, through the two component theory of the neutrino, came major advances in understanding of  $\beta$ ,  $\pi$  and  $\mu$  decay and a satisfactory formulation of low energy weak interaction processes.

A detailed account of this stage in the development is now the subject of a book by one of the early pioneers of the theory of  $\beta$  decay—Professor Konopinski. This spells out step by step each stage in the rather complicated calculations including all effects which might be expected to give a measurable contribution. The basic assumptions of the theory are compared with experiment wherever possible and the reader is provided with all those tools of the weak interaction trade appropriate to the low energy domain (although  $\beta$ -circularly polarized  $\gamma$  correlation theory is omitted).

More recently the interrelation of weak interaction theory with other branches of particle physics has led to many important developments. The present fashion for current-current commutation relations has its roots in the work of Goldberger and Trieman in connexion with  $\pi$  meson decay, and the ideas of unitary symmetry have, through the Cabibbo angle, explained why even small differences in coupling constants which occur in the theory of transitions conserving strangeness are nevertheless significant. Perhaps most important of all has been the suggestion by analogy with electrodynamics that the weak interactions are mediated by an intermediate vector boson. This, together with the availability of high energy neutrinos from the big accelerators and in the cosmic ray flux, has led to what is now another branch of high energy physics—neutrino physics.

The volume by Wu and Moszkowski is a review of the subject to this point. With the advantage of a much broader canvas, they have presented an extremely readable account of both the theory and the more recent experiments. The formal details required for a reasonable understanding of the processes by which the relevant numbers are arrived at are reserved for appendixes, a historical introduction is provided and so also is a final chapter on recent developments written, as the authors put it, "with great emotion and enthusiasm". The book is completed by an excellent bibliography.

It is only to be expected, in this field in particular, that nature should have the last word. In 1964, experiments on the decay of neutral  $K$  mesons by Christensen and collaborators demonstrated unexpectedly the apparent failure of time reversal invariance, a rather curious echo of the " $\tau$ - $\theta$  puzzle", presented by the decay of the charged  $K$  mesons, which led to the developments associated with the breakdown of parity conservation. If certain recent conjectures by Lee are verified, and the experimental evidence is at present conflicting, our understanding of the basic invariance properties of the interactions of elementary particles must shortly undergo another major upheaval.

G. N. FOWLER

## PUTTING TO SLEEP

### Animal Anaesthesia

By Melchior Westhues and Rudolf Fritsch. Vol. 2: General Anaesthesia. Translated by A. David Weaver. Pp. xxi+458. (Edinburgh and London: Oliver and Boyd, Ltd., 1965.) 95s.

THIS is the second of two volumes entitled *Die Narkose der Tiere*. The first volume is concerned with local

analgesia and this second work is devoted to general anaesthesia. Dr. A. David Weaver has now made an excellent translation of both volumes. The subject matter of the present book is well presented and is divided into four parts with an introductory chapter on the history of anaesthesia. Part I deals with the principles of anaesthesia including the application of physics and physiology. Part II considers drugs which may be used in anaesthesia and Part III describes techniques and accidents and complications associated with anaesthesia. Part IV is concerned with the application of anaesthesia to different species including, in addition to the domesticated animals, small laboratory ones, wild or captive creatures, birds, fish and frogs.

The authors have attempted a comprehensive coverage of the subject of general anaesthesia in animals, and since the volume is of moderate size it is not surprising to find that many aspects are dealt with briefly. It is perhaps unfortunate, however, that this should have been the case with such important topics as the general preparation and post-anaesthetic care of the patient. Some of the techniques, such as endotracheal intubation are poorly described, while others, notably those describing the use of barbiturates in horses, could lead to serious trouble if carried out literally. In addition, some surprising statements are to be found, for example: "As a direct result of its unphysiological breeding, the pig is a very poor subject for general anaesthesia". Terminology is sometimes at variance with that generally accepted among anaesthetists, for example, no distinction is made between ventilation and respiration and the term "forced ventilation" is used instead of "controlled ventilation".

The pharmacology of anaesthetic agents is well described and the appendix contains a useful list of drugs. The bibliography is extensive, but selection of a particular reference is tedious since they are listed together at the end of the book. This book contains much useful information and is well illustrated, but the general standard of the text is variable.

BARBARA M. Q. WEAVER

## INTEGRAL EQUATIONS

### Integral Equations and their Applications

Vol. 1. By W. Pogorzelski. (International Series of Monographs in Pure and Applied Mathematics, Vol. 88.) Pp. xiii+714. (London and New York: Pergamon Press Ltd.; Warszawa: PWN-Polish Scientific Publishers, 1966.) 120s.

THIS book is a translation from the Polish of three separate volumes which appeared between 1953 and 1960, and so divides naturally into three parts. The aim of the book is to present the general theory of integral equations, together with their applications. Special techniques, such as the use of Fourier transforms, which lead to explicit solutions in certain cases, are not considered.

The first part gives an account of the theory of Fredholm integral equations. The Fredholm theory for equations of the second kind and the Hilbert-Schmidt theory for symmetric kernels are given in some detail. Other topics treated here are Fredholm equations of the first kind and Volterra equations. The treatment in this part is classical, little use being made of functional analysis. This section could well serve as an introduction to the theory of linear integral equations, and may be read without previous knowledge of the subject.

The second part is chiefly concerned with applications of the integral equations studied previously to the theory of linear ordinary differential equations and to second order linear partial differential equations of all three types. The treatment of partial differential equations is given in considerable detail with discussions of the reduction of many of the classical boundary value problems to inte-

gral equations. This part also includes a treatment of non-linear equations by use of functional analysis and the Banach and Schauder fixed point theorems.

The third part deals mainly with strongly singular linear integral equations, that is, equations containing an integral which converges only as a Cauchy type limit. These equations are then applied to several problems in potential theory. There is also a section on strongly singular non-linear equations.

As this description of the contents shows, the range of topics considered is wide. The book should be useful as a reference work with a broad coverage for applied mathematicians, physicists and engineers, and in particular to those interested in the treatment of partial differential equations by integral equations.

V. HURSON

## SOVIET MAMMALS

### Mammals of the U.S.S.R. and Adjacent Countries

Mammals of Eastern Europe and Northern Asia. By S. I. Ognev. Vol. 4: Rodents. Translated from the Russian by Jean Salkind. Edited by O. Theodor. Pp. x+429+61 tables. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1966.) 142s.

THIS volume, the fourth on rodents in the series of *Mammals of the U.S.S.R. and Adjacent Countries*, deals with the pikas, hares, rabbits, squirrels and chipmunks. Although basically a systematic work, it is a great deal more besides. The disparate nature of systematic accounts and general biological works are blended together in such a way that the bare bones are well clothed. Details are given of morphology, taxonomy, ecology and behaviour as well as valuable information not readily available on the role of these rodents as agricultural pests. There are accounts of the cyclic nature of hare populations and of epizootics in fluctuations. Not least is the detailed zoogeographical information which is one of the chief contributions of this volume and of the series as a whole. Like its predecessors, this book is a mine of information of the greatest value to the mammalogist.

The text is generally easy to read. Many of the field observations are verbatim accounts by the original observers and this makes for some pleasant changes in style. There are many tables and these are clear and comprehensive.

The small single page maps of other volumes have been replaced by larger detachable folding maps. Increase in size has unfortunately not been matched by increase in clarity—the shading in some cases is coarse and obscures geographical detail. The book is well illustrated by a variety of contributors. Many of the drawings are delightful, although a few are of more artistic than scientific value. Some of the original colour plates, now in black and white, have been so darkened that they serve little purpose and could have been omitted without detriment. These are, however, minor matters and do little to detract from the great value of the volume and the series.

G. I. TWIGG

## ELECTRON MICROSCOPY COMPENDIUM

### Techniques for Electron Microscopy

Edited by Desmond H. Kay. Second edition. Pp. xiv+560. (Oxford: Blackwell Scientific Publications, 1965.) 84s. net.

MY first reaction to the second edition of this book is critical, in that metallurgists are forced to pay (handsomely) for a great deal of information on the preparation

of biological specimens, and microbiologists for information on metallurgical techniques. A glance at the table of contents will show, however, that those pages useless to either type of microscopist comprise less than a quarter of the whole, so that this particular compendium of articles appears to be well justified.

The second edition differs from the first chiefly by the addition of an article by Howie on the interpretation of micrographs of thin crystals. This article is the best short account of the subject now available. Some of the other articles do not reconcile so well the conflicting roles of elementary exposition of theory and up to date description of advanced techniques. This difficulty could be alleviated to some extent by the inclusion of a list of standard books in which the interested reader can find treatments of the various theoretical topics at a suitable level. (I have in mind such topics as the scattering of electrons by atoms, general principles of diffraction, etc.)

A casual reading of the book reveals very few errors. The book is also quite up to date, although inevitably some recent developments (particularly those concerning ancillary apparatus and special attachments) are not included. A casual reading also reveals those areas in which further technical advances would be most welcome; in the measurement of magnification, for example.

The book is certainly essential for any laboratory using electron microscopy. It is an extremely good introduction to experimental techniques for research students, and for other research workers trying unfamiliar methods.

L. M. BROWN

## CARBANIONS

### Carbanions in Synthesis

(Oldbourne Chemistry Series.) By D. C. Ayres. Pp. viii + 207. (London: Oldbourne Press, 1966.) 52s. board; 25s. limp.

Clearly, a considerable degree of condensation and compression is required to deal with such a far-ranging topic as the role of carbanions in synthesis in a book of 207 pages. This is most noticeable in the first main chapter of *Carbanions in Synthesis*—forty-two pages on the formation, stereochemistry and reactions of the metal alkyls—in which the selection of the material covered seems a trifle capricious, to say the least. In the section entitled "Stereochemistry of Metal Alkyls", for example, the only stereoisomers of metal alkyls mentioned are the optical isomers of substituted cyclopropyl derivatives of lithium and magnesium; there is no reference at all to the widely investigated secondary butyl compounds of mercury, although work on these latter compounds has led to a much better understanding of mechanisms of reaction in organometallic chemistry.

The succeeding chapters, 152 pages, making up the bulk of the book, form a somewhat separate section or classical organic syntheses. Here Dr. Ayres seems to be much more at ease, and deals convincingly with established topics such as the synthetic uses of acetylides, malonic esters, diazomethane, and the various carbonyl condensation reactions, as well as with more recent developments in the form of the Wittig reaction, arynes, carbenes, and so forth.

Reaction mechanisms are considered wherever appropriate and, indeed, help to unify the treatment on the "carbanion" theme. As illustrations of the various general reactions and methods, specific examples, often from natural product chemistry, are invariably quoted, and each chapter ends with a useful selection of problems together with the original sources of the problems. Second-year and third-year undergraduates should find the book, in general, both interesting and informative.

M. H. ABRAHAM

## ALGORITHMS

### Introduction to Cybernetics

By Viktor M. Glushkov. Translated by Scripta Technica, Inc. Translation edited by George M. Kranc. Pp. x + 322. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 94s.

THIS book is really an introduction, not to cybernetics as it is known in the West, but to the theory of algorithms. As such it covers mathematical logic, from the propositional calculus to the Gentzen formalization of the predicate calculus and the decision problems, Post, Turing and Markov algorithms, Boolean algebra, switchings nets, and the elementary theory of finite sequential automata, and some aspects of the theory of self-organizing or self-improving systems. There is also a chapter on Algol programming, as an example of a universal language for representing algorithms on a general-purpose digital computer.

In general, this is not a book which is suitable for the uninitiated. Most of the chapters are too concise, and there are not nearly enough examples to work through. The sections dealing with Boolean algebra applied to switching nets, and the theory of finite automata, leave much to be desired. There is no treatment of threshold logic, which has so many applications in the construction of actual automata, nor of the algebra of finite automata, centred around the Rabin-Scott/Schutzenberger introduction of finite semi-groups and the subsequent Kron-Rhodes canonical decomposition theory.

The book is, however, well worth reading for its main chapter—that dealing with self-organizing systems. The well known Perceptron is analysed in detail, and it is clearly shown that there are severe disadvantages in the use of randomly connected nets for pattern recognition, even if there is an external trainer. It is also shown that if there is no external trainer, the Perceptron is the least likely automaton to achieve correct pattern recognition. In this respect this volume will be useful to those interested in artificial intelligence, but not necessarily to those interested in the wider aspects of control and communication in animals and machines.

### Engineering Materials

Selection and Value Analysis. Edited by H. J. Sharp. Pp. 428. (London: Heywood Books, for Iliffe Books, Ltd.; New York: American Elsevier Publishing Company, Inc., 1966.) 85s. net.

THIS book is intended to serve two purposes: it provides, for the benefit of designers and materials engineers, a concise body of factual information about the properties of commercially available constructional materials, and it also seeks to expound the philosophy of "value analysis" applied to materials selection as a means of finding the cheapest material to fulfil a precisely defined function adequately. The first purpose is served better than the second; nevertheless, the importance of economic considerations is emphasized throughout the book, and information on comparative costs is listed in many places.

The chapters on various categories of materials are uneven in quality. The best is that by P. C. Thornton on constructional steels, which can serve not only as a useful source of data, but also as a lucid primer on the principles of selection and heat treatment of steels. Several other metallurgical topics, such as bearing alloys, are also well treated, and indeed the book has a strong metallurgical bias, in spite of the fact that the editor contributes a useful summary of the properties of modern plastics. The editor also contributes a critical survey of materials processing methods. Engineering ceramics and glasses and composites (other than fibreglass) receive no attention.

Apart from these omissions, and the more general criticism that there are no detailed case histories of material selection and associated design improvement, this book can be recommended as a useful concise source book for designers, and a refresher for metallurgists who wish to be reminded of the uses of their science.

### Advances in Enzymology and Related Subjects of Biochemistry

Vol. 28. Edited by F. F. Nord. Pp. v+547. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1966.) 115s.

VOLUME 28 of this series contains seven chapters. Laylin K. James and Leroy G. Augenstein discuss the adsorption of enzymes at interfaces. This is timely, because biochemists are increasingly conscious that the dilute aqueous solution in which they study enzymes is an artificial environment compared with the gels in which those enzymes occur in nature.

E. R. Stadtman deals with the allosteric regulation of enzyme activity. His article is restricted to a consideration of those regulatory processes that involve reversible metabolic activation or inhibition of the enzyme activity. Tsao E. King considers the problem of the reconstitution of the respiratory chain, but limits himself to the mitochondria of animal tissues.

Nathan Citri and Martin R. Pollock review the biochemistry and function of  $\beta$ -lactamase (penicillinase). Alan T. Bull and C. G. C. Chesters deal with laminarin and laminarinase and focus attention on the biosynthesis and depolymerization of  $\beta$ -1,3-glucans. Von Ed. Hofmann and Gg. Hoffmann review (in German) the estimation of biological activity in soil using enzyme assays. Henry Z. Sable gives an account of the biosynthesis of ribose and deoxyribose excluding those studies which attempt to assess the relative proportions of glucose metabolized by the glycolytic and pentose cycle pathways. The volume maintains the standard to which biochemists have long been accustomed in this series.

T. J. BOWEN

Dissatisfaction with students who only wanted a qualification from his course, repugnance for biological work, and the wish to run his own department encouraged Hodkinson to accept the post of professor and head of the Department of Physics at Virginia State College. He was the first full-time white faculty member to be appointed. During his two years in this Negro college the benefit to the students was immense. He gave them first class visiting lecturers and a Federal research grant, revived his department, and, revealing a musical and poetic talent, contributed to the artistic life of the college. He was, however, impatient with the college administration and criticized it for its acceptance of low academic standards, an authoritarian rule and the assignment of funds to architectural features rather than to learning. When last year he decided to take a sabbatical year he was dismissed from his post. He went to Sweden, and it was while sailing alone in his yacht that he died.

C. N. DAVIES

### Isaac Pomeranchuk

ISAAK YAKOVLEVICH POMERANCHUK, who died on December 14 aged 53, was one of the outstanding theoretical physicists of the Soviet Union. Born in 1913, he graduated from the Polytechnical Institute in Leningrad in 1936, and then did research in several institutes of the Academy of Sciences. His last appointment was in the Institute of Experimental and Theoretical Physics. He was awarded the Stalin Prize, and since 1953 had been a corresponding member of the U.S.S.R. Academy of Sciences.

His interests ranged widely over the whole of theoretical physics. His earliest known contributions concerned the theory of solids and in particular the problem of the thermal conductivity of dielectrics, for which he pointed out a number of important facts which had been overlooked. He worked also on the related problem of the absorption of sound waves, and did some early work on the scattering of neutrons by crystals. Other papers relate to such diverse subjects as the properties of liquid helium, the "Delbrück scattering", and the effect of the emission of radiation in limiting the energy of primary cosmic ray electrons reaching the Earth. In recent years his work was mainly concerned with the physics of elementary particles and in particular with the theory of collisions at high energy. His best known result in this field is the proof, surprisingly simple and powerful, that collision cross-sections at high energy, if they reach finite limits for infinite energy, must become the same for particles and antiparticles on the same target. Another important result is contained in joint work with Gribov, which showed that scattering amplitudes regarded as analytic functions of angular momentum may contain not only poles ("Regge poles") but also essential singularities which invalidate some of the conjectures fashionable at the time. These are a few examples of a prolific output of work, which was broken only by his final and fatal illness.

His approach was always to emphasize simple physical arguments and to pick out the general features of the type of situation which could throw light on the physical problems, without becoming involved in too much detail. He was capable of carrying through a sophisticated mathematical argument when this was necessary, but he never regarded this as an aim in itself. In this respect his attitude showed very much the influence of L. D. Landau, with whom he collaborated on many occasions.

As a person he was held in deep affection by all his colleagues. He was modest to the point of self-deprecation and careless about appearances. The figure in a crumpled suit who always managed to look as if he had last shaved two days ago, but who always had something sensible and relevant to say, will be sadly missed at all gatherings of physicists.

R. E. PEIERLS

## OBITUARIES

### Dr. J. Raymond Hodkinson

RAY HODKINSON was drowned in the Baltic on August 24, 1966. He had planned to spend a year in Sweden and write a book about the measurement of airborne dust.

From the Grammar School he went to the University in Manchester and graduated in physics in 1949. He worked briefly with Associated Electrical Industries and at Jodrell Bank, before his national service in the Royal Air Force. He entered the Safety in Mines Research Establishment at Sheffield in 1952, and here he rose rapidly. His work was concerned with dust physics and the use of radioactive tracers to investigate the ventilation of mines. On his promotion to principal scientific officer he was allowed to spend nearly three years at the London School of Hygiene to undertake research into the scattering of light by particles. Some of his ideas he put into effect on his return to Sheffield.

In 1962 he obtained his Ph.D., and in the same year he went to the Department of Radiation Biology at the University of Rochester, to take charge of aerosol physics. He stayed there until June 1964. During this time he travelled extensively in the United States and Canada to visit laboratories and speak at scientific meetings. His knowledge of the optics of particles was useful to the U.S. Public Health Service, for whom he became a consultant, and he went to Canada with an eclipse expedition. With Judith Greenfield he used a computer to calculate the response of optical particle counters using a variety of light systems.

# A Mechanism for Radio-galaxies and Quasars

by  
W. H. McCREA  
University of Sussex

Gravitational collapse and thermonuclear processes, operating through the formation of many temporary stars, can provide a basis for a model of radio sources. The model may explain some of the properties of the sources and provide a unifying theory for quasars and radio-galaxies

THIS article presents what seems to be a possible explanation of the phenomena of radio-galaxies and quasars. While the theory is speculative at present, it does nevertheless succeed in correlating many empirical properties without invoking any hitherto unknown processes or states of matter.

Lynds and Sandage<sup>1</sup> and others have found direct evidence for the occurrence of violent events in the central regions of certain galaxies. Less direct, but accumulating, evidence tends to show that when such an event occurs, the galaxy concerned may become a strong radio-galaxy or a quasar, and that it may also become a strong X-ray source and possibly a cosmic-ray source. Thus these events seem to underlie and to correlate a wide range of features in the large scale behaviour of certain galaxies. A satisfactory theory of any of them seems, therefore, to require the understanding of the physical nature of such an event.

The predominant characteristic of an event of the kind considered is that it releases an enormous amount of energy in a cosmically short time. It seems that the radiation rate is of the order of  $10^{46}$  ergs/sec during an interval of from  $10^3$  to  $10^6$  years, and that the total energy requirement is about  $10^{50}$  or possibly as high as  $10^{52}$  ergs. The only known processes which can release large quantities of energy, and in which the material taking part is in some state or another known to physics and astronomy, are those which release gravitational energy or nuclear energy. The gravitational energy released in forming stars and galaxies is not enough for the present requirement. On the other hand, if the material of a galaxy of  $10^{11}$  solar masses was originally mainly hydrogen, and if all of it were converted into helium and heavier elements with the release of energy equivalent to about 1 per cent of the mass, then the total energy released would be more than  $10^{52}$  ergs. There is, therefore, an ample source of energy; this has long been appreciated, and the problem is to discover how the source can be made use of. Two processes are essential to the solution I propose.

**Gravitational contraction.** Consider a mass  $M$  of material, mainly atomic or molecular hydrogen, occupying a cylindrical volume of height  $2h$  and diameter  $2R$ ; numerically, take  $M=10^8 M_\odot$ , where  $M_\odot$  is the solar mass,  $h=R=10$  parsecs. Let the initial density be roughly uniform, and let any pressure gradient be small compared with the force of self-gravitation of the material. Thus the material is effectively in a state of free fall under its own gravitation. Let any initial motion of the material be small, but let it be such that the material is falling towards its equatorial plane. We can then treat the subsequent motion as being mainly towards this plane, because this tends to flatten the distribution and the flatter it becomes the more predominantly the attraction tends to be towards the equatorial plane. If  $t$  is the time for the material to fall the distance  $h$  from either side to the equatorial plane, we find  $GMt^2=hR^2$  approx., where  $G$  is the gravitation constant;  $t$  is the characteristic time for the process we are considering. In our example,  $t$  is about  $5 \times 10^4$  years. The gravitational energy released in the passage to a highly flattened state is of the order of

$\frac{1}{2} GM^2 h/R^2$ , which is  $10^{56}$  ergs using the numbers suggested. Material that falls the full distance  $h$  reaches the equatorial plane with speed about  $(2 GM h/R^2)^{1/2}$ . In the example, this is about 300 km/sec, and the escape-speed from any point on the outside of the initial configuration also has about this value, while the escape-speed from the centre after the system has become highly flattened is about 400 km/sec.

The material will thus tend after about the time  $t$  to form a thin disk of radius about  $R$ . But a thin disk some 10 parsecs in radius would obviously not be a stable state, and before the state is reached the material will therefore fragment into many portions. Each of these portions will proceed to collapse gravitationally on to itself, or will at least tend to do this.

**Temporary stars.** The only fate which we know for a body of material such as we are considering is that most of it should go to form stars. Also we know that no

normal star can have mass greater than some value  $M_{\max}$ , where  $M_{\max} \approx 50 M_\odot$  according to the usual estimate. Consider then two fragments of the sort mentioned at the end of the last section, fragment  $A$  having mass  $M_A$  well above  $M_{\max}$ , and fragment  $B$  having mass  $M_B$  well below  $M_{\max}$ . By definition,  $A$  and  $B$  both start on similar courses of gravitational collapse. In the case of  $B$  this leads to a comfortable career as a normal star. In the case of  $A$ , we know in advance that the material cannot form a single normal star and so that it must sooner or later disintegrate. But the material itself does not know in advance that it cannot form a star. It can discover this only by trying to form a star; it will then discover that its mass is too great, and its only resort is to break up. The material cannot be said to have tried to form a star until it has begun to release energy. It will scarcely discover that it cannot form a star by releasing only gravitational energy, because the gravitational energy released by such a contracting body is not sufficient completely to disperse a large part of its mass. We conclude that at some stage before contraction is halted, nuclear energy generation will start near the centre.

Thus we get a "star" with large mass  $M_A$  and with thermonuclear energy generation proceeding in its central part. Because of the large mass, the rate of energy generation is very great, and as already inferred, the star can have only a temporary existence and will break up. Because of the rapid generation of energy, we infer that the break-up will be explosive.

An estimate which seems plausible is that the explosion will occur after the hydrogen has been used up in a central region of mass about equal to the Chandrasekhar limiting mass  $M^*$ , which is about  $1.2 M_\odot$ . There is no reason for expecting any catastrophe before that, while there is the possibility of catastrophic processes after that. On this estimate, the energy released by the temporary star in its brief career would be about  $0.01 M^* c^2$ , or about  $2 \times 10^{52}$  ergs.

It is natural to compare the inferred explosion of a temporary star with the observed explosion of a supernova. Ginzberg and Syrovatskii<sup>2</sup> quote the energy generated by a number of supernovae as having exceeded  $10^{50}$  ergs and even reached  $10^{52}$  ergs. The nuclear processes preceding a supernova outburst are presumably not the same as those preceding the explosion of a temporary star, but the fact that my estimate shows somewhat more energy to be associated with the explosion of a body of somewhat more mass lends plausibility. It also indicates that the effect of the exploding temporary star should be generally similar to that of a particularly powerful supernova.

*Fragmentation of contracting system.* Suppose that we are dealing with a case in which the fragments of the gravitationally flattened system first formed mostly exceed  $M_{\max}$  in mass. Most then become exploding temporary stars. Some of the material thrown out by the earlier explosions will become enmeshed by the collapsing material in the system, and it will fall back with this material. This is because the energy released in any one explosion is inadequate to check significantly the collapse of any large part of the whole system. Consequently, much of the material may participate more than once in the explosion temporary stars.

As a rough estimate of the total number of explosions  $N$  we shall take  $N \approx M/M_{\max}$ . This is the optimum number of first-time explosions. Although we do not expect to get all these explosions first time, this will be compensated by the fact that some of the material goes through the process more than once. In our example,  $N \approx 2 \times 10^6$ , so the total energy emitted would be about  $0.01 N M^* c^2$ , which is  $4 \times 10^{58}$  ergs for the figures quoted. This would be emitted in time of the order of  $t$ , say  $2t$  in order to make allowance for material taking part in more than one explosion. This gives a mean rate of emission of about  $0.01 N M^* c^2 / 2t$ , or about  $10^{46}$  ergs/sec for the figures chosen. In this example, the values  $N \approx 2 \times 10^6$ ,  $2t \approx 10^6$  y give about 20 explosions a year, so that there would be fluctuations of brightness of the system rather more than once a month on the average.

*Proposed model.* The suggestion is that a violent event in a galaxy is produced by the formation and explosion of a large number of temporary stars in a contracting mass of gas near the centre of the galaxy.

It is further suggested that while the eruptions are in progress the system forms a quasar, and the optical emission is mainly that coming directly from the rapid generation of energy in the temporary stars. It is suggested that the system subsequently becomes a radio-galaxy. In both stages, the radio-emission would be produced by relativistic electrons ejected by the explosions and continuing to radiate for some considerable time afterwards. Thus, at any particular epoch, the optical emission from a quasar would come from a few explosions, perhaps with only one predominating, that happened to occur near that epoch. The radio emission, on the other hand, would come from the relativistic electrons produced in many explosions, perhaps all those that have already taken place up to that epoch. Remembering that we envisage the explosions occurring in a region of the order of magnitude of only 10 parsecs across, it is seen that the electrons from the various explosions will rapidly become intermingled in some sort of cloud enveloping the whole system. The subsequent behaviour of this cloud must depend on the ambient features of the particular galaxy, principally, no doubt, its magnetic field.

*Properties of the model.* Evidently a model of the sort proposed can produce the required rate of energy release over the expected time interval. This is shown by the numerical example, and similar results would be obtained from other starting conditions.

We have also seen that the model gives about the observed frequency of fluctuations in the optical emission of quasars. These fluctuations are produced by the succession of peaks of emission from the succession of exploding temporary stars, with a more or less random distribution in time. If the explosions do show similar peaks of emission to supernova explosions, it seems that the model could give the observed amplitude and the frequency of fluctuations. On the other hand, if the peaks were somewhat less pronounced, or the frequency somewhat greater, then the fluctuations could easily become blurred. So the model is not contradicted by quasars which show no detectable fluctuations.

It seems that supernovae of a given type have a fairly standard pattern of behaviour; the same might be expected of the temporary stars we are considering. If at any epoch the optical luminosity of a quasar is produced predominantly by one such "star", it follows that the peak luminosity of a quasar may be a fairly standard quantity. There is evidence that this agrees with observation<sup>3</sup>.

From the account of the radio emission given in the preceding section, it is seen that in the case of a quasar the fluctuations in the radio emission would not closely match those of the optical emission. In fact, we should not expect to find short lived fluctuations. Also, because of the additive effect of successive explosions, during much of the career of a quasar we should expect a fairly steady increase in radio emission. I believe that all these inferences have some observational support.

According to our model, in a radio-galaxy as distinct from a quasar there are no fresh injections of relativistic electrons, so we expect only a slow, and probably undetectable, decline in power.

The inference that radio sources within the Milky Way Galaxy like the Crab nebula are ex-supernovae is now generally accepted. So, neglecting the foregoing discussion, we might simply assert that a radio-galaxy is so similar to an enormously powerful Crab nebula that, had a whole battery of supernovae been fired off, instead of just one, we should have produced a radio-galaxy. Moreover, remembering that the maximum optical brightness of a supernova may exceed that of the entire galaxy in which it occurs, we can see that during the outbursts we should have something very like a quasar. For we know that it is the excessive optical emission that mainly distinguishes a quasar from a radio-galaxy. Also, if the supernovae were fired off in rapid succession, we should reproduce the rapid optical fluctuations of a quasar.

G. R. Burbidge<sup>4</sup> advanced such ideas at one stage. There is no known way, however, in which supernovae could trigger one another to produce the battery effect needed. By contemplating temporary stars rather than supernovae we appear to secure all the merits of Burbidge's scheme while also finding a natural way in which many eruptions may be associated.

If then we may think of a quasar as consisting of a gigantic "crab nebula", then, by comparison with the actual Crab nebula, we infer that the material of the "nebula" is expanding outwards. It is indeed part of our suggestion that the material seen to be ejected from, say, the galaxy M82 is produced by the same mechanism. Actually, observers have recently reported absorption features in the spectra of quasars that indicate the presence of material moving outwards at very high speed (about 1,000 km/sec), thus giving further support to the model (see, for example, Bahcall, J. N.<sup>11</sup>).

Another essential feature of the model is that the main processes occur in or near a disk. This means that the resultant outward flow would tend to be normal to the disk. This would account in principle for the axis of some sort that so many radio sources possess. There must be a magnetic field if there is to be synchrotron radiation; if the field is strong enough, the outflow would be along the lines of force giving the jets that characterize some sources.

We infer that the emission features in the spectra of quasars arise in the gas in the immediate vicinity of the temporary stars. We have seen that the gas falling into this region has a speed of several hundred kilometres per second, so we should predict considerable Doppler widths for these features; again this is observed. In other respects we should expect the optical spectrum of a quasar to be generally similar to that of a supernova, and this seems to be the case. Furthermore, in our model, while the optical emission of a quasar comes directly from the explosions, the radio emission depends on the conditions that develop in the system as a whole. In particular, if the magnetic field in the system is too weak, we should not get detectable radio emission, but the optical emission would be unaffected. This could account for "quasi-stellar galaxies" that give no detectable radio effects.

If a violent event is produced in the manner suggested, there is no reason why a particular galaxy should not be the scene of several such events at various epochs. Actually, the concept of a radio-galaxy as the scene of multiple outbreaks has been suggested by several detailed studies made by Ryle and his colleagues<sup>5</sup>.

*Concept of exploding stars.* Ebert<sup>6</sup> gave a highly instructive treatment of gravitational contraction of material under external pressure. I then found<sup>7</sup> that the amount of material that could be made to collapse by Ebert's process, in the conditions that he envisaged in interstellar space, would have to be some hundreds of stellar masses. I then suggested that this quantity of matter might form an exploding temporary star, to the fragments of which Ebert's process could be applied afresh to produce normal stars. I published an account of only the first part of this work because I became convinced that the "angular momentum difficulty" defeated the second part; I eventually proposed to overcome this difficulty in a different way<sup>8</sup>. Nevertheless, I mentioned the original idea at the Solvay Conference of 1958 and at that time T. Gold expressed similar views.

A recent stimulating discussion with Dr. D. Lynden-Bell and Dr. I. W. Roxburgh reminded me of these ideas. In the context of the present work, much greater bodies of material are concerned than in the earlier work. The conversation with my colleagues led me to think of contraction towards a disk as a first stage, and to think of its fragmentation as a second stage to which my former ideas might apply. There may still be an angular momentum difficulty, but this may perhaps be resolved by the operation of whatever magnetic field is present.

Observers do have evidence of material flowing into the nucleus of a galaxy, and they do also see material that has been violently ejected. So the availability of material and the occurrence of violent events are not speculative. Also, it is scarcely speculative to say that if the material is present it must ultimately either form normal stars or disperse. Star-formation demands

fragmentation of the material. If at some stage some fragments are more massive than  $M_{\max}$ , then the consequences we have been discussing seem to be almost inevitable. It even seems that the particular masses of the initial fragments (so long as some exceed  $M_{\max}$  are not of great importance; for, as we have said, if some are greatly in excess of  $M_{\max}$ , their material will compose temporary stars more than once.

Thus the operation of the mechanism is qualitatively plausible, while our discussion has shown that the consequences qualitatively and quantitatively appear to be in good agreement with observation. As to the quantitative realization of the starting conditions, we are clearly dealing with rather rare experiences in the history of a galaxy, for at any epoch perhaps only one galaxy in  $10^8$ – $10^9$  can be a strong radio source or a quasar; less spectacular occurrences of similar phenomena may, of course, be quite common.

An attractive feature of these ideas is that they would closely link the phenomena of radio-galaxies and quasars. Nevertheless, there are at present few positive observational links, and there is even an absence of links that might be expected. Crucial tests of the ideas might be had from further observational examination of possible connexions. Theories of quasars that invoke some energy-source other than nuclear energy all seem to require some process or state of matter not yet known to occur. A mechanism requiring a new physical process is that discussed by Hoyle and Narlikar<sup>9</sup> depending on the non-conservation of baryons. A mechanism requiring a special state of matter is any that ascribes the energy production of a system to the mutual annihilation of matter and antimatter. Any mechanism that appeals to the release of gravitational energy in the required quantities leaves the material concerned in a state the existence of which has not been verified. This applies whether we consider energy release from a single very large mass, or from a compact cluster of many bodies, so long as the subsequent release of nuclear energy is not invoked. A theory that does appeal to nuclear processes is that of Wyller<sup>10</sup>.

## Synthesis of Dolomite

by

O. LIEBERMANN

29 De Vere Gardens,  
Cranbrook,  
Ilford, Essex

When the solubilities of calcium and magnesium carbonates approach one another, dolomite will precipitate directly from solution. In sea water this happens at a minimum salinity of four to six times that of normal sea water and when the pH after effective abstraction of carbon dioxide is 8–9

WORK carried out in the past on the synthesis of dolomite under conditions prevailing in marine sedimentary environments has been completely unsuccessful<sup>1</sup>, although synthesis has been achieved at high temperatures and pressures. The experiments carried out by Zeller *et al.*<sup>2</sup> and by Siegel<sup>3</sup>, although using mild or relatively mild conditions, were

not representative of a sedimentary environment because of the peculiar composition of the solutions used in these experiments.

My working hypothesis for the formation of marine dolomites is based on three fundamental postulates. (a) Precipitation of a crystalline compound from an

Fig. 1. Solubilities of calcium carbonate and magnesium carbonate in pure water and in sea water at 25°C as functions of carbon dioxide partial pressures. (Data for magnesium carbonate in sea water only available for atmospheric  $p(\text{CO}_2)$ .) *a*, Calcium carbonate in sea water (ref. 10); *b*, calcium carbonate in pure water (refs. 7 and 10); *c*, magnesium carbonate in pure water (ref. 8); *d*, magnesium carbonate in sea water (ref. 11); *e*, magnesium carbonate in sea water (ref. 4).

aqueous solution implies that the compound must be in true ionic solution at the moment of precipitation. The same principle applies to any double or multiple salt and the often quoted equation for the dolomitization reaction

is not strictly correct. Assuming that the magnesium ions are supplied by sea water, the dissolved magnesium sulphate will be used up first and then the magnesium chloride, as indicated by the schematic equations

and

(b) If dolomite or any other double or multiple salt is to separate out from solution as a solid, its solubility must be lower than the solubility of its constituents. In the case of dolomite this condition is easily satisfied because its solubility is much lower within a wide range of partial pressures of carbon dioxide, salinities and temperatures than of either magnesium carbonate or calcium carbonate. (c) The relative solubilities of the constituents of the double or multiple salt should be equal or nearly equal at the moment of co-precipitation; that is, in the case of dolomite, the molar solubilities or the solubility products of calcium carbonate and magnesium carbonate should be approximately equal before precipitation starts.

The calculation of the solubilities of calcium carbonate and magnesium carbonate in hypersaline sea water from the equilibrium constants encounters serious difficulties because activity coefficients have only been published for these compounds in normal sea water. Apart from this, one must expect that the various interionic relationships will become more involved as interionic distances decrease and that relevant data for normal sea water<sup>4,6</sup> will have

to be modified and supplemented to become applicable to hypersaline sea water.

Instead of attempting such an approach, use was made of previous solubility determinations<sup>6-13</sup>. The results of these determinations have been assembled in the form of four graphs (Figs. 1-4).

Fig. 1 shows that an increase in the partial pressure of carbon dioxide causes a gradual, although diminishing, divergence of the solubility curves, magnesium carbonate always remaining more soluble in pure water than calcium carbonate. The same certainly applies to the solubilities in sea water, although solubility of magnesium carbonate has only been determined at atmospheric pressure of carbon dioxide.

Fig. 2 confirms the theoretical demand that the solubility of calcium carbonate in pure water should be higher than in a solution saturated with respect to calcium sulphate. It also shows that the difference in solubilities is almost the same over a wide range of  $p(\text{CO}_2)$ . Because of the nearly identical solubilities of calcium carbonate in pure water and in sea water (Fig. 1), it may be concluded that the removal of calcium sulphate from sea water will cause an increase of the solubility of calcium carbonate which is of the same order as the one shown in Fig. 2.

For the study of the influence of salinity of sea water on the solubility of calcium carbonate, data are only available which extend up to 60 parts per thousand salinity. For magnesium carbonate none could be found at all, only solubility determinations in sodium chloride solutions of varying concentrations (Fig. 3). Use was made of these, however, because it may be safely assumed that the behaviour would be similar in sea water, even if the absolute values differ slightly. It can be seen from the graph that at approximately 110 parts per thousand salinity two events take place which seem to contribute to a definite approach towards equal solubilities. At this point the solubility of magnesium carbonate reaches a peak and starts to decrease at a fast rate, while the solubility of calcium carbonate, after the start of precipitation of calcium sulphate, should increase sharply. Although it is highly hypothetical because of the lack of more precise information, the configuration suggests that the two solubility curves will meet eventually, possibly at a salinity of approximately six times the salinity of normal sea water.

In Fig. 4 the firm lines represent the solubilities of calcium carbonate and magnesium carbonate in sea water in relation to pH. No information seems to exist on the influence of pH on the solubilities of the carbonates in hypersaline sea water. Hypothetical curves with dotted lines have therefore been drawn to show in a schematic way the expected changes, that is, the increased solubility of calcium carbonate after the start of precipitation of calcium sulphate and the increased solubility of magnesium carbonate (in the range of salinities from normal to five or six times the normal salinity of sea water).

Fig. 2. Solubilities of calcium carbonate in pure water at 20°C (+---+) and in a solution saturated with respect to calcium sulphate at 25°C (x---x), as functions of carbon dioxide partial pressures (ref. 7).

Also shown is the highly probable nullification of this effect by an increase of  $pH$ . Both sets of curves lead to the same target, namely, a meeting point in the region of  $pH = 9.0$ .

The hypothesis which forms the basis of the experimental work has been formulated as follows. The formation of dolomite is a two-step process: the first step consists of the dissolution of calcium carbonate deposits by hypersaline sea water and the second step in the co-precipitation of calcium carbonate and magnesium carbonate. The second step can only take place if the three fundamental postulates listed before are satisfied.

The dissolution of calcium carbonate is furthered by low temperatures, high partial pressure of carbon dioxide, and low  $pH$  apart from such factors as increased salinity and higher pressure. The co-precipitation of the carbonates is promoted by elevated temperatures, low partial pressure of carbon dioxide, and high  $pH$ , apart from other less important factors. The first set of conditions may prevail during cool periods or at night, whereas the second set of conditions will be prevalent during warm periods of the season or in the daytime generally. Photosynthetic activity of certain algae able to survive high salinities may play an important part by abstracting

carbon dioxide from the solution in daytime. This activity will be at rest during the night, while increased carbon dioxide tension promotes the dissolution of calcium carbonate. Decay of organic matter on a large scale will result in the production of carbon dioxide and ammonia, the decay being caused by the mass death of marine organisms swept into the restricted coastal area by the inflowing sea water and immediately killed if the salinity of the water exceeds 70 parts per thousand. There are not many organisms which tolerate higher salinities.

The aim of the laboratory procedure was the synthesis of dolomite under conditions which appeared characteristic for coastal areas with restricted water circulation during periods of aridity. The necessary acceleration of the natural process of dolomite formation was achieved by a strict regulation of the two alternating steps and by helping the dissolution of calcium carbonate in every possible way within reasonable limits.

Using reagents of analytical quality, artificial sea water was made up to the following formula:

	(g)
Sodium chloride	26.83
Magnesium chloride	3.21 (using $MgCl_2 \cdot 6H_2O$ )
Magnesium sulphate	2.24 (using $MgSO_4 \cdot 7H_2O$ )
Calcium sulphate	1.23 (using $CaSO_4 \cdot 2H_2O$ )
Potassium chloride	0.76
	34.27

Fig. 3. Solubility of calcium carbonate in mixohaline, normal and hypersaline sea water at 25°C (a, refs. 10 and 13) compared with solubility of magnesium carbonate in sodium chloride solutions of varying concentrations at 23°C (b, ref. 6). (Comparable data for solubility of magnesium carbonate in sea water not available.)

Fig. 4. Solubilities of calcium carbonate (a) (ref. 9) and magnesium carbonate (b) (ref. 11) in normal sea water at 25°C and hypothetical solubilities of calcium carbonate (c) and magnesium carbonate (d) in hypersaline sea water of 4-6 times normal salinity as functions of  $pH$ . (Purely schematic as far as hypothetical curves and areas are concerned.)

the salts being dissolved in purified water to make up 1,000 g. For solutions of higher concentration multiples of the salt mixture were dissolved in purified water and made up to 1,000 g. Calcium sulphate was omitted from many solutions to study the effect of an excess of calcium ions; also none was added to the solution in experiment 57, which was six times the original concentration of sea water. Calcium carbonate in the form of fairly fine calcite crystals was added to each solution in such proportions as to satisfy the dolomitization reactions (2) and (3). Finally, in agreement with the fact that sea water has a preponderance of cations over anions (which gives rise to  $pH$  values ranging from 7.8 to 8.2), the  $pH$  of the solutions was adjusted using a concentrated sodium carbonate solution, aiming at  $pH$  values slightly higher than in normal sea water. This proved impracticable, however, with solutions of higher concentration than three times the original concentration, unless unreasonably high proportions of sodium carbonate were added. Also, after completion of the first series of experiments it was noted that the  $pH$  of all solutions had dropped to values ranging from 7.8 to 7.3. Therefore, in the experiments which followed an additional adjustment of  $pH$  was made in the form of a few drops of diluted ammonia, added to each flask regularly after the completion of the first step and after a certain warming up. This procedure resulted in maintaining a  $pH$  of slightly above  $pH$  8.0 in all mixtures at the time they reached the precipitation stage (step two).

Conical or flat-bottomed round flasks of 500 ml. capacity, fitted with doubly perforated rubber bungs and inlets and outlets for carbon dioxide gas, were filled with 350 g of the experimental solution plus the calculated amount of calcium carbonate. The weight of each flask was then recorded. Each series of experiments consisted of eight flasks linked in series to a carbon dioxide steel cylinder, from which a slow stream of gas was bubbled through the mixtures at a rate of 20-30 bubbles per min. A reaction temperature of 5°-10° C was maintained by cooling with ice. The duration of this first step was 6 h in initial experiments and 12 h in later experiments. The dissolution of calcium carbonate was also helped by occasional shaking of the flasks. After completion of the first step, the flasks were transferred to an electrically heated drying oven, the temperature of which was thermostatically controlled at 43° C  $\pm$  2° C. The flasks were left at this elevated temperature for approximately 60 h, then taken out and the small evaporation losses

made good by the addition of purified water; *pH* measurements in later experiments were carried out at all stages of the process, but only at the start and at the end of the first series.

The temperatures used in these experiments may correspond to actual water temperatures reached at night and in daytime in shallow pools and basins. Maximum temperatures estimated or recorded by various investigators average 40°–50° C (refs. 1 and 14) and may even rise to 70° C under special circumstances. The gradual concentration of the brine by evaporation in the natural environment was duplicated by the use of a range of solutions of definite salt concentrations. The supply of carbon dioxide gas during the first step was undoubtedly more generous in the experiments than in a natural environment. This exaggeration of natural conditions, however, served only to accelerate the dissolution of solid calcium carbonate without affecting the course of events in a fundamental way. Thanks to these measures, one single cycle of dolomite formation took only three days and the accumulating effect was such that one can estimate a total conversion of the calcium carbonate to dolomite as within a few months.

The experiments were performed in an attempt to obtain information on whether it is possible to reproduce the process of dolomite formation in nature by a relatively short laboratory run, envisaging that the process takes shape in alternating steps of dissolution of calcium carbonate and co-precipitation of calcium carbonate and magnesium carbonate. Furthermore, an answer was sought to the question whether the dolomitization reaction is confined to certain limits of salinity as indicated by geological and other evidence; and if it is, then both the lower and the upper limit of salinity could be defined. Also investigated were the effect of an excess of calcium ions, namely, the presence of dissolved calcium sulphate, on the dolomitization reaction, then the suggestion that the presence of ammonium salts, such as ammonium chloride, was absolutely necessary for dolomitization<sup>15</sup>, and finally the effect of *pH* on the course of dolomitization.

Tables 1 and 2 contain all the relevant data of the laboratory experiments.

Some interesting facts emerge from the available data. It has been proved that magnesian calcites, disordered dolomites and probably also well ordered dolomites may be synthesized by a two-step process as already described. The magnesian calcites (as shown by No. 25, Table 1) include some with extremely high contents of magnesium carbonate. The formation of the magnesian calcites and dolomites is very much dependent on the salinity of the sea water. According to X-ray examination, none was formed at normal salinity, although chemical analysis indicated the presence of more than 1 per cent of magnesium carbonate in sample No. 50 after 17 cycles. Whatever the form of this substance is, it may have some

connexion with the presence of the unidentified line at 4.52 Å; however, dolomite formation definitely starts at twice the normal concentration of sea water: weakly if calcium sulphate is present, but quite vigorously if it is left out of the mixture of salts. Production of disordered dolomites appears to reach a peak at three to four times the original salinity, but here again, only if calcium sulphate is not present. As stated before, this condition corresponds to events taking place in the natural environment as soon as 110–120 parts per thousand salinity has been reached. At higher salinities, at least at a salinity of six times the normal concentration of sea water, dolomite is formed at a much reduced rate, but possibly in a condition approaching that of ideal dolomites. The amount of it produced after fourteen cycles was insufficient to prove this point, but sufficient to show the initiation of the main reflexion (104) at 2.88 Å which is characteristic of ideal dolomites. It is also obvious that an upper limit of salinity for the formation of dolomite has not been found in these experiments because it is quite likely that still higher concentrations than six times the normal salinity of sea water may be suitable for this purpose, even if the rate of formation is further reduced. The inhibiting influence of dissolved calcium sulphate is drastically demonstrated by a comparison of numbers 24 and 29, 20 and 22, 52 and 53, 54 and 55. The excess of calcium ions in solution reduces the solubility of calcium carbonate to such a degree that the solubility product remains far below that of magnesium carbonate. The presence of ammonium chloride is not absolutely necessary for the formation of dolomite, although it may be slightly beneficial, as shown by a comparison of numbers 24 and 25, also of 20 and 28.

While the last eight experiments were progressing it was realized that the *pH* at the moment of the start of co-precipitation of calcium carbonate and magnesium carbonate should have reached a higher value than just above *pH* = 8 attained in most samples. Such an adjustment, however, proved a difficult matter because after completion of the first step the *pH* values had dropped in most samples to below *pH* = 6.0. The addition of more ammonia than of a few drops at this stage seemed undesirable because of the possibility of precipitation of basic magnesium carbonates or even magnesium hydroxide. A satisfactory solution of this buffering problem has yet to be found for most salinities, possibly with the exception of six times the normal salinity of sea water. In this latter case the combined effects of increased salinity and slightly increased alkalinity, separately shown in Figs. 3 and 4, may have already created reasonably favourable conditions for the formation of ideal dolomites. The lack of continued *pH* adjustment in the course of the initial experiments has not only adversely affected the quantity but also the quality of the magnesian mineral, as can be seen from a comparison of numbers 24 or 25 with 55. Even in the last experiment

\* Based on analyses by R. Curtis from smear-mounted samples run at 2°/min on a Philips diffractometer, using copper K $\alpha$  radiation and pulse height discrimination. Additional runs were made of No. 25 at 0.25°/min with and without internal standard.

the results are far from perfect because, owing to the changing laboratory procedure, the dolomite-like products are non-uniform and tend to form broad peaks on X-ray examination. The estimates of dolomite-like products in the solid phase from peak heights do not agree with estimates from chemical analyses. The former are consistently lower and it is suggested that the unusual breadth of the peak may be the cause.

As early as 1917 (ref. 16), N. Kurnakov has found that in the Perekop lakes of the Crimea dolomite was formed by the reaction of calcium bicarbonate carried by rivers with the magnesium salts of the lake. In this special case the dilution of the brine by river water is not critical because the brine represents a highly concentrated solution of magnesium chloride. The difference between dolomite formation in the Perekop lakes and by the two-step process is that in the former case calcium carbonate is being supplied to the brine in a dissolved state, whereas in the second case the brine effects the dissolution of solid calcium carbonate. Even in the Perekop lakes dolomite would be formed by a modified two-step process, probably caused by differences in temperature, corresponding to night—and day—conditions. It may be assumed that this process universally applies to coastal areas with restricted water circulation, as well as to inland lakes which represent remnants of ancient seas.

In connexion with the two-step concept of dolomite formation certain geological problems appear in a new light, among them the deposition of calcium carbonate of organic and inorganic origin, porosity and texture of

dolomites, their role as reservoir rocks for petroleum, the composition of oil-field waters and other problems.

I thank the management of Berger, Jensen and Nicholson, Ltd., who supplied working space, equipment and materials for the initial experiments carried out in their Group Analytical Laboratory; Dr. G. F. Claringbull, of the British Museum (Natural History), for a preliminary X-ray analysis of some initial samples; D. J. Shearman, of the Department of Geology, Imperial College of Science and Technology, for helpful discussion and the loan of equipment; and R. Curtis, of the same institute, for his painstaking X-ray analyses of samples submitted.

# Mylonite Zones and Mylonite Banding

by

M. R. W. JOHNSON

Grant Institute of Geology,  
University of Edinburgh

Mylonite layers show evidence of thinning and flattening. They are thought to develop approximately perpendicular to the direction of principal stress much the same way as in the development of cleavage in slate

MYLONITE zones have been recorded from many parts of the world. They occur in association with both thrust and wrench faults, and more rarely, as narrow zones which are quite independent of fractures. They exist in both low-grade (for example, the Moine thrust) and high-grade<sup>2</sup> metamorphic environments.

The common misuse of the term mylonite has been noted by Christie<sup>3</sup>; many cataclastic rocks are incorrectly referred to as mylonites (for example, the zone at the base of the Morcles nappe in the Swiss Alps, first recognized by Lugeon, is not composed of mylonite). In Lapworth's<sup>4</sup> definition, mylonite is a banded micro-breccia—that is, it possesses “fluxion structure”. I accept that the presence of banding is crucial but question whether its significance has been properly understood. Lapworth did not explicitly assign a dynamic significance to the banding; he noted that “mylonites formed along thrust planes when two superposed rock systems moved over each other as solid masses”. Later writers have stressed the “rolling out”, “milling”, “differential movements” that were supposed to have operated along the mylonite banding. Turner and Verhoogen<sup>5</sup> define mylonite fabrics as “rock fabrics of *S*-tectonite class that have evolved under the influence of penetrative movement on one set of parallel or sub-parallel *s*-surfaces”; of the banding they say that the “fluxional lamination . . . reflects a sliding movement in a single set of parallel *s*-planes”, also the bands are “surfaces of strong differential movement”. As a general comment on the origin of mylonite zones they state that “notable relative displacements with which they (mylonites) commonly are associated have been distributed through but small thicknesses of rocks”. The latter notion on the origin of the zones is echoed in the use of the term “movement-zone” for the mylonites along the Moine thrust<sup>1,3,6</sup>. Obviously a considerable vagueness persists on the topic of mylonites. But, although nowhere stated explicitly, it seems reasonable to suppose that the common presumption is that mylonites have developed along surfaces of high resolved shear stress<sup>7</sup>, that is parallel to thrust faults.

A simple application of Coulomb theory<sup>7</sup> to mylonite zones is open to general objections, in the same way that the application of the theory to geological fractures is far from satisfactory. It is generally supposed that faults and mylonite zones are alternative expressions of planes of high resolved shear stress in a stress field; the mylonites reflect creep fracture, well known in experimental investigations and characteristic of shear under higher confining pressure and temperature and slower strain rates than the brittle fractures. Alternative theories of brittle fracture in solids, for example, the Griffith theory of fractures<sup>8</sup> or the principle of least work (compare with Kehle<sup>9</sup>), considerably complicate the simple Andersonian concept of faulting. These doubts make it important to reconsider the orthodox interpretation of mylonite zones and mylonite banding.

There are two possible fallacies in the “simple shear” hypothesis for the origin of mylonite zones. The milling and grinding of pre-existing crystals involved in mylonit-

ization do not necessarily involve the operation of a component of high shear stress parallel to the banding, and the streaking out of comminuted rock flour along the banding is more consistent with the banding being a surface of low resolved shear stress, that is, a surface of elongation. Second, it is well known that resistant particles and minerals in mylonites possess an ovoidal shape, for example, porphyroclasts of feldspar in mylonitized granites. The ovoidal porphyroclasts are ellipsoidal, with the longer dimensions parallel to the banding and the shortest dimension roughly perpendicular to it. This pattern of dimensional orientation is also seen in smaller porphyroclasts and in the matrix aggregates of quartz. The banding looks like a coarse slaty cleavage and if this analogy is accurate then the following question arises. Does mylonite banding have the same origin and kinematic significance as slaty cleavage? The evidence in favour of the positive answer to this question may be reviewed by discussing the mylonites from the Moine thrust zone, which have been extensively investigated. Since the nineteenth century it has been apparent that slaty cleavage develops normal to the direction of shortening or in planes of low resolved shear stress<sup>10,11</sup> (along cleavage surfaces rock particles have undergone elongation; compare Cloos's oolites<sup>12</sup>). The relevant evidence as to whether mylonite banding also develops along a plane of low resolved shear stress is summarized here.

The precise geometrical relationship of mylonite banding to fold axial planes is generally unknown. Christie<sup>13</sup> describes the development of “schistosity” in intrafolial folds in the mylonites at the Stack of Glencoul, Assynt, as follows. “During slip on the slip surface, . . . , the surfaces become unstable and bend into flexural slip folds (Biegefallen). . . . A new schistosity develops by shearing of the limbs of the smallest-scale folds. . . . This schistosity is more stable than the original, but it is rapidly rotated toward the plane of the latter”. This description should be clarified as follows. First, the “new schistosity” is the mylonite banding. Second, the “slip surfaces” are bedding planes (which, contrary to Christie's view, give the colour banding in the Stack mylonites). Third, the distinction of bedding (“slip surfaces”) and mylonite banding (“new schistosity”) is obvious in fold cores, but, of course, on the fold limbs the two surfaces are subparallel. These observations can be confirmed in mylonitic rocks from many parts of the Moine thrust zone, also in Torridonian, Lewisian<sup>1</sup>, Cambrian and Moine rocks in this zone. Generally mylonite banding follows a pre-existing compositional layering (foliation in gneisses or bedding in sediments), but at fold cores it transects the layering and thus simulates axial plane cleavage. The postulated analogy between mylonite banding and slaty cleavage is supported by the dimensional orientation of particles in mylonites and mylonite gneisses, a point noted above. Commonly ovoidal porphyroclasts have tails which are normally made up of a recrystallized aggregate of quartz and feldspar which extend out along the banding from the porphyroclast,

tapering-off gradually<sup>1</sup>. The banding curves around the ovoid and the tails, which are sheltered areas, or "pressure shadows", in which macro-crystals have grown. Such a structure is more in accord with the flattening which operates normal to the banding than with the notion of "shear planes" flowing around the porphyroclasts. In fact the ovoids are akin to boudins and they may, indeed, represent relics of once continuous layers of relatively competent material<sup>1</sup>. The "boudins" have become widely separated. Pinched-out forms are also exhibited by small porphyroclasts; and the recrystallized quartz grains in the matrix sometimes show elongation in the direction of the banding. If the banding was a surface of simple shear one could predict that the longest dimensions of particles would lie at an angle to the banding (again, compare the oolites in the South Mountain Fold<sup>12</sup>). Additional evidence that the banding is a surface of tensile strain is that the larger feldspar ovoids in mylonites are commonly split open by tension cracks, which are infilled by notably large quartz grains and lie at a high angle to the banding. Also there are (?) shear fractures in the porphyroclasts: the banding tends to bisect the obtuse angle between intersecting fractures.

The conclusion is that considerable elongation has taken place along the banding during mylonitization; the so-called "streaking out" of rock-particles on the banding shows that the latter was a direction of extension in the strain-field. In terms of the deformation ellipsoid, the longest axis was parallel to the banding. It should be possible to define the deformation ellipsoid fairly accurately using the shapes and orientations of porphyroclasts. In some mylonites there is no obvious preferred orientation of the longest axes of feldspar ovoids. This suggests that extension was permitted in various directions in the banding, which therefore contained the *zy*-plane of an oblate deformation ellipsoid (*S*-tectonites in Flinn's terminology<sup>14</sup>). Other mylonites exhibit a marked linear tendency in the longest dimensions of ovoids (*L*-tectonites). Thus, for the Moine thrust belt, at least, the shapes of the deformation ellipsoids vary from  $K = \infty$  to  $K = 0$  (ref. 15). Possibly the constriction-type deformation ( $1 < K \leq \infty$ ) has been superimposed on a primary *S*-tectonite fabric.

The quartz microfabric in the mylonites from the Moine thrust belt exhibits orthorhombic symmetry. Christie<sup>13</sup> interprets this microfabric as implying non-translative movements following an episode of translative movement expressed by folding. If the orthorhombic quartz microfabric reflects the presence of a flattening component in the folding process, however, there is no need to postulate two episodes for deformation<sup>14</sup>. The orthorhombic microfabric, in which one symmetry plane coincides with banding, accords with the interpretation of mylonite banding as being a plane of flattening.

Further evidence on the kinematic significance of the main foliation in the Moine thrust zone (that is, the foliation—including mylonite banding—and the synchronous schistosity developed outside the actual mylonite zones) is forthcoming from study of the deformation of "pipes" in the Cambrian quartzites. These pipes have previously been neglected although they are useful strain markers.

The pipes have been rotated nearly parallel with the bedding, involving a rotation through 90°. During rotation the pipes have been distorted from an originally cylindrical shape into flattened sheets, some so thin that they resemble leaves of tobacco. The plane containing the pipes is a cleavage, and is obviously a plane of flattening. In some localities the cleavage is roughly parallel to the bedding (for example, above the Moine thrust on the Stack of Glencoul); elsewhere it is oblique to bedding. The progressive deformation suggested by the pipe deformation is that of rotation (and related flattening) of pipes towards an equilibrium position sub-parallel to the bedding, that is, into a sub-horizontal attitude. This

can be depicted as a path of structural movement for a line (pipe) on Flinn's diagrams—the line rotates towards the *zy*-plane of the deformation ellipsoid ( $1 \geq K \geq 0$ ). It may be mentioned that the path of structural movement for the pipes lies in a vertical plane running W.N.W.–E.S.E. and this is perpendicular to the "deformation plane" deduced for the folds (compare Christie<sup>13</sup>).

There is no doubt that the interpretation of the banding in mylonites as a surface of flattening strain applies to mylonites from other places.

In conclusion, a few comments on the general setting of mylonites in the Moine thrust zone are useful in this context. The mylonite zones are zones of intensive flattening ( $0 \leq K < 1$  modified to  $1 < K \leq \infty$  in certain domains) and are not necessarily related to any large scale translative movements. It must be realized, however, that unless mylonitization is accompanied by volume reduction the development of the mylonite zones results in "translative" movement, that is, the flattened mylonitized zone must be displaced relative to the undeformed surrounding rocks.

The development of mylonite zones is correlated with the progressive increase in flattening strain encountered in a traverse from west to east across the Moine thrust zone, that is, structurally upwards. For example, in the Loch Alsh area<sup>6</sup> it is possible to recognize the following changes: (a) in the west around the core of the large-scale Loch Alsh fold there is only weak flattening, clastic grains are undeformed and cleavage is not strongly developed; (b) eastwards across the inverted Torridonian in the Loch Alsh fold flattening becomes more intense, clastic grains are deformed, a strong cleavage is found and various quartz vein systems have rotated towards the plane of cleavage while in some localities (for example, Ard Hill, Balmacara) extensive variations in the axial trends of early folds have resulted from passive rotations of the axes during elongation of the rocks along cleavages; (c) in the overlying Lewisian rocks flattening varies in intensity and is most marked in thin mylonite bands which are oriented roughly parallel to the axial plane of the Loch Alsh fold.

If the discussion is extended to take account of displacement in orogenic belts, then the inferred picture of movement (involving pure compression and extension) for mylonites suffers from the same defects as the generally favoured "flattening hypothesis" for slaty cleavage development. Thus it fails to distinguish between rotational and non-rotational strains. For example, in both pure strain and simple shear it is predicted that composite surfaces with complex kinematic histories can be generated. For example, in progressive simple shear, planes of "flattening" may be rotated into near-parallelism with shear planes. Although such factors complicate the dynamic analysis of geological structures, the deduced picture of movement for simple, regionally developed surfaces like slaty cleavage and mylonite banding probably reflects a uniform strain history for these surfaces.

Drs. R. Cheeney and G. Oertel made helpful comments.

# Causes of Birefringence in Diamond

by

A. R. LANG

H. H. Wills Physics Laboratory,  
University of Bristol

By optical and X-ray techniques many different causes of strain birefringence in diamond can be distinguished. The perfect diamond, free from strain, is an elusive ideal

In a recent paper, Tolansky<sup>1</sup> reports that of 5,000 good quality diamonds he examined, not one was found free from birefringence. Any strain except uniform dilatation will produce birefringence in diamond. Tolansky's observations become less surprising when viewed against the evidence accumulated in the last couple of decades both for the diversity of strain-producing defects in diamond and for their inhomogeneity of distribution in any stone. The "perfect" diamond becomes ever more elusive as it is pursued with increasingly sensitive tests for imperfection. This article attempts to describe some characteristic patterns of birefringence in diamond and to explain them in terms of the distribution of the particular strain-producing defects responsible for them. The types of defect causing strain have been classified, for convenience, into five groups: (i) dislocations, (ii) lattice parameter variations, (iii) precipitates and inclusions, (iv) fractures and (v) plastic deformation.

(i) *Dislocations*. Many diamonds show a concentration of strain birefringence near their geometric centre. Birefringent regions sometimes extend outwards from this centre, like rays. An association of such patterns with dislocations radiating from the crystal nucleus was first suggested by Frank, Puttick and Wilks<sup>2</sup>. Correctly interpreting as etch pits the pyramidal pits which form one class of the equiangular-triangle-bounded pits known as "trigons" commonly observed on natural octahedral faces, they noted that in a specimen possessing a cluster of trigons on every face, each cluster lay roughly at the foot of the perpendicular dropped from the central strain nodulus to the face concerned. Such a disposition of pits would be expected if they were the outcrops of "grown-in" dislocations generated at the imperfect nucleus and subsequently entrained in the crystal along lines radiating outwards to the growing faces. The association suggested by Frank *et al.* was confirmed by X-ray topography<sup>3</sup>. Further X-ray topographic studies, in which the correspondence of dislocation outcrops with apices of pyramidal trigons was demonstrated<sup>4</sup>, and also more recent investigations on both whole stones and sections, have shown that there are many specimens in which radiating bundles of dislocations were obviously the agencies responsible for the major manifestations of birefringence in the specimen.

Fig. 1a shows a birefringence topograph of a polished slice of clear white diamond cut from the girdle region of an octahedron. The print is a positive: black means extinction between crossed polarizers; light is failure to extinguish, that is birefringence. The contrast of the print has been enhanced so as to display better the set of rectangular "frames" of relatively weakly birefringent lamellae which cover most of the section, and which arise from variations in lattice parameter (ii). Visual observation shows that the birefringence is strongest at the centre of the "star" and decreases somewhat outwards along its rays. From the X-ray topograph (Fig. 1b) it appears that this slice has included the nucleus of the crystal, and that it is dense bundles of dislocations radiating from the nucleus that produce the birefringence star. The greater sensitivity

and topographic resolution of the X-ray technique enable the bundles to be resolved into individual dislocations where they are less dense, and disclose in various parts of the slice many individuals which escape detection by birefringence. A uniaxial strain of only one part in  $10^6$  should produce measurable birefringence in a diamond plate 1 mm thick. Such high sensitivity to strain can be realized with simple optical apparatus when the field observed contains strains differing by this amount or more; for then, with strong illumination and careful exclusion of scattered light, the small variations in extinction over the area of the specimen can be recorded directly by high contrast photography. The X-ray diffraction method requires strain gradients for the production of contrast:

Fig. 1. Diamond slice cut parallel to (001), edge length 6 mm, thickness 1 mm. a, Birefringence topograph. b, X-ray topograph, 400 reflexion, molybdenum K $\alpha$  radiation.

only inhomogeneous strains can be detected, but with a sensitivity that surpasses that of the optical method. An earlier report<sup>4</sup>, dealing with observations on complete natural octahedra, stated that "possibly some hundreds of dislocations are required to produce noticeable birefringence". With polished slices, which are free from strains due to surface damage, it appears possible to detect by birefringence small bundles of dislocations the resultant Burgers vector of which is perhaps only 3 or 4 unit Burgers vectors.

(ii) *Lattice parameter variations.* The concentric rectangular "frames" which appear in Figs. 1a and, better resolved, in Fig. 1b are traces of octahedral planes. Such patterns, together with those produced by etching polished slices<sup>5,6</sup>, give a valuable stratigraphic record of the growth history of the stone. They testify to non-uniform conditions of growth, with consequent non-uniform concentrations of incorporated impurity. The record in Figs. 1a and b is unusually simple for diamond: it suggests growth with unchanging regular octahedral habit. A more complicated history, involving a change from rounded to octahedral habit, is indicated by the birefringence, X-ray diffraction and ultra-violet absorption topographs of one of the specimens investigated by Takagi and Lang<sup>7</sup>, and is displayed in striking form in the etch patterns of Tolansky<sup>1,6</sup> and some of those of Seal<sup>8</sup>. (A straightforward explanation of the geometry of Seal's and Tolansky's etch patterns has recently been put forward by Frank<sup>9</sup>.) The chemical nature of the impurities whose non-uniform incorporation produces strain in Fig. 1 cannot be discovered from birefringence and diffraction topographs. Neither can it be stated whether they are incorporated on an atomic or coarser scale, except that the state of division must be finer than about  $1\mu$ . Larger aggregates would probably produce strain fields which could be individually resolved by both the X-ray and optical techniques. It is pertinent to recall the pioneer birefringence topographs of Raman and Rendall<sup>9</sup> and the X-ray topographs of Ramachandran<sup>10</sup>. Raman and Rendall's specimen D179 (shown in their Fig. 1) contains a central concentration of birefringence like that shown in Fig. 1a here. Ramachandran's X-ray topograph of D179 shows a corresponding central region of strong diffraction contrast, but does not resolve dislocations. Raman and Rendall's specimens D174, 178 and 179 show growth stratifications parallel to octahedral faces, forming concentric octahedral shells. Ramachandran's careful determination of the sign of the uniaxial birefringence of individual lamellae interspersed in diamonds (Type I) opaque to ultra-violet showed that some lamellae are in a state of tension and some in compression<sup>11</sup>. This certainly suggests that more than one type of impurity is responsible for the differences in mean lattice parameter of adjacent layers of diamond, from which differences the coherency strains arise. Mismatch of this sort can be accommodated by arrays of dislocations lying in the surface separating regions of different lattice parameter. An array probably performing this function is seen in plan in Fig. 7 of the article by Takagi and Lang<sup>7</sup>. Others, seen edge-on, appear in Fig 2c. The slice of which the birefringence, ultra-violet transmission and X-ray diffraction topographs appear in Figs. 2a, b and c, respectively, had the same thickness and orientation as the slice shown in Fig. 1, but was somewhat larger. It was also much more imperfect, containing cracks and large inclusions whose strainfields dominate the birefringence pattern Fig. 2a and which, as seen in the X-ray topograph Fig. 2c, cause either strong diffraction contrast or, in some regions, a misorientation sufficient to tilt the region away from the Bragg reflecting position altogether. The one impurity known to be present in variable concentration is nitrogen, since its presence, when precipitated in platelet form<sup>7,12</sup>, is associated with ultra-violet absorption<sup>13</sup>. The ultra-violet transmission topograph Fig. 2b (kindly provided by Dr. W. Kaiser) shows a roughly square band of relatively highly transmitting material. This appears because the slice cuts through an octahedral

Fig. 2. Diamond slice roughly parallel to (001), edge length 9 mm, thickness 1 mm. a, Birefringence topograph. b, Ultra-violet transmission topograph. (Blackening on image corresponds to high transmission.) c, X-ray topograph, 220 reflexion, silver  $K\alpha$  radiation.

shell, roughly 1 mm thick, in which the nitrogen concentration is about  $2 \times 10^{19}$  atoms/c.c., which is about a fifth of that ( $\sim 10^{20}$  atoms/c.c.) in the more absorbing central and outer parts of the slice. (Diagonal striae on Fig. 2b are to be ignored: they arise from refraction at saw-cut grooves on the specimen faces.) A relatively steep nitrogen concentration gradient appears to be present at the lower, horizontal outer boundary of the band. This boundary correlates with the innermost of three horizontal bands of blackening on the X-ray topograph. From this and other topographs it appears that these bands contain arrays of dislocations; some of the dislocations in each band become entrained in the growing crystal and form the "cascade" of dislocations seen in the lower part of Fig. 2c. The regions of high gradient of nitrogen concentration, that is the inner and outer boundaries of the transmitting octahedral shell cut in Fig. 2b, have no manifest correlation with any feature on the birefringence topograph Fig. 2a, though the strains due to cracks and inclusions may be masking small birefringence variations. It is clear, on the other hand, that the bands of strongest diffraction contrast (note especially the bands running vertically near the left margin of Fig. 2c) and which correlate well with bands of birefringence on Fig. 2a, have no corresponding feature on Fig. 2b. If they are associated with abrupt changes in nitrogen concentration, then such changes must be confined within layers not more than about  $10\mu$  thick in order to escape detection in the ultra-violet transmission topograph (Fig. 2b) assuming that the layers are parallel to octahedral planes and hence make  $35^\circ$  with the specimen normal.

(iii) *Precipitates and inclusions.* The strains arising from incorporation of inclusions large enough to be easily visible optically are an obvious cause of birefringence. Such inclusions may or may not be the source of dislocations generated by lattice closure errors arising as the foreign body is enveloped by growing crystal: this question will be answered by X-ray rather than birefringence topography. Generation of dislocations at inclusions is very common. Small bodies in the micron range of size are a cause of birefringence less readily identified optically. These small bodies may be inclusions mechanically incorporated at the growing crystal surface, or precipitates formed after growth: the distinction can probably be made if dislocations are present. Inclusions often are a source of grown-in dislocations, as already mentioned, whereas precipitates are observed strung along previously grown-in dislocations, like beads on a thread<sup>14</sup>. In general only the larger strain centres visible on X-ray topographs can be correlated individually with those detected by birefringence<sup>7,14</sup>.

(iv) *Fractures.* Strains associated with internal cracks produce both X-ray diffraction contrast and visible birefringence. Cracking is frequently found in the otherwise rather perfect cores of coated diamonds<sup>15</sup>. Natural diamonds have suffered much surface damage: edges are burred and faces bear many percussion marks in the form of partial or complete ring cracks. On X-ray topographs of such surfaces, it is only too evident that all faces are peppered with images of ring cracks. It is found that ring cracks the diffraction images of which spread  $25\mu$  or more wide on topographs taken with molybdenum  $K\alpha$  or silver  $K\alpha$  radiation produce, individually, clearly visible birefringence figures. Cracks of such magnitude occur with a density around  $10/\text{mm}^2$  of surface. To the extent, then, that all natural diamonds have damaged surfaces, all are birefringent. (It may be noted that the birefringence generated by deliberately produced ring cracks with diameters of  $100\text{--}200\mu$  is extremely intense<sup>16</sup>; but the birefringence produced by the strainfields of micro-abrasions<sup>17</sup> is quite slight.) If cleavage occurs in an irregular fashion, as it does when diamond plates fail during bending experiments<sup>18</sup>, strong birefringence and diffraction contrast are generated by strains associated with subsidiary cracks accompanying the fracture<sup>19</sup>. It is

thus not unexpected that a high incidence of birefringence is found among diamond chips (that is, cleavage fragments)<sup>1</sup>.

(v) *Plastic deformation.* A type of birefringence found in many Type II (nitrogen-poor) stones<sup>9,11,20</sup> is exemplified in Fig. 3. Such specimens were called "laminated diamonds" by Ramachandran. A descriptive term proposed<sup>7</sup> for this pattern which avoids any suggestion of connexion with growth layers is "tatami"—after the Japanese rice straw mat. The birefringence is very strong. In Fig. 3 it occurs in lamellae dominantly parallel to one octahedral plane. In other specimens equally well developed intersecting birefringent lamellae parallel to more than one octahedral plane can occur. Ramachandran reported that lamellae occasionally occur parallel to dodecahedral planes. Significant features of the tatami pattern are that lamellae parallel to different crystallographic planes intersect each other and also that they cut right through growth stratifications. The latter occurrence could be demonstrated with the specimen of Fig. 3 which was found by M. Takagi to contain some growth layers with a sufficient nitrogen platelet content to show up in ultra-violet transmission topographs. They formed a series of roughly concentric shells centred about a point slightly to the right of the centre of Fig. 3. The similarity of the tatami birefringence patterns to those produced by slip-bands in plastically deformed transparent crystals<sup>21</sup> is so close that its explanation, proposed by Frank, as due to varying amounts of slip, on one or more slip planes, at some stage after growth, appears irresistible. The lower plastic yield stress of nitrogen-poor diamonds (which often show tatami patterns) compared with nitrogen-rich diamonds<sup>18</sup> could account for the greater probability of finding plastic deformation in the former.

Fig. 3. Birefringence topograph: "tatami" structure. Specimen width 8 mm, thickness 1 mm.

Another type of birefringence pattern found in Type II diamonds is shown in Fig. 4. This is very weak: an exposure forty times that of Fig. 3 was needed to record the pattern, and it could easily escape notice. It was the highly imperfect crystal lattice, found by X-ray topography to approach the ideal "mosaic", that first attracted attention<sup>19</sup>. The X-ray and birefringence topographs look rather alike. There is some overall long range warping, but the characteristic feature is the division of the whole specimen into cells ( $\sim 10\mu$  diameter) in the walls

Fig. 4. Birefringence topograph: "annealed" structure. Specimen width 4 mm, thickness 0.5 mm.

of which reside strains, and, presumably, dense, unresolvable dislocation networks. It is believed that this pattern represents an annealed plastically deformed crystal: strains have been greatly reduced compared with those seen in Fig. 3, and the dislocations have been largely re-arranged to lie in cell walls which bear no obvious relation to the original slip planes.

The foregoing account has indicated the variety of causes of birefringence of diamond. Tolansky's<sup>1</sup> invocation of an ever present intermixing of Type I and Type II layers is unnecessary. Indeed there is evidence that it is not generally present. Growth in layers alternately poor and rich in nitrogen platelets, repeating with a period of 5 $\mu$  or less, would be detected by electron microscopy<sup>12</sup>; and if such occurred with a larger period, and was accompanied by strains sufficient to produce birefringence, it would be detected by X-ray topography. Sharp gradients of platelet concentration do, however, exist at particular

growth horizons<sup>7,12</sup> and a single such gradient in the specimen should produce observable birefringence unless dislocation arrays exactly compensate the dimensional mismatch across the boundary where a given number of unit cells of pure diamond meets the same number of cells of a mixture including some cells of platelet<sup>22</sup> structure with those of pure diamond. But birefringence demonstrably arising from other causes is usually observed.

## Flavins in a Solid Matrix

by

G. R. PENZER

G. K. RADDA

Department of Biochemistry,  
University of Oxford

Organized aggregates of flavins and other chromophores play a part in the functioning of biological photoreceptors; this has prompted a study of photochemistry and energy transfer of flavin molecules in methyl cellulose films

THE increasing awareness that chromophores in biological photoreceptors form part of an organized or semi-organized system led us to examine the photochemistry of flavins in transparent films of methyl cellulose. The solution photochemistry of these compounds is quite well understood<sup>1</sup>.

**Properties of the films.** Thin (0.0025 cm) transparent films of methyl cellulose can be prepared by spreading a layer of aqueous methyl cellulose solution (2.25 g/100 ml.) on a glass plate, and allowing it to dry. If the solution contains other compounds, then they are included in the film. Methyl cellulose is hygroscopic, and after atmospheric drying the films retain 5 per cent water by weight (measured by heating to constant weight) which shows as an absorption at 1,640  $\text{cm}^{-1}$  in the infra-red spectrum of the film<sup>2</sup>. Flavin mononucleotide (FMN) does not alter the infra-red spectrum of an empty film except to superimpose the flavin absorptions which are at 1,545, 1,580, 1,640 and 1,710  $\text{cm}^{-1}$  (ref. 3). Compared with the spectra in water the visible absorption band of FMN is unchanged in methyl cellulose ( $\lambda_{\text{max}}$  447  $\text{m}\mu$ ), but there are small shifts in the near ultra-violet band (375–368  $\text{m}\mu$ ) and in the fluorescence emission (530–535  $\text{m}\mu$ ). These shifts are compatible with the film providing a less polar environment than an aqueous solution<sup>1</sup>.

It might be expected that trapping a chromophore in a solid film would considerably restrain, if not completely prevent, its molecular motion (translation and rotation). The fluorescence polarization of FMN and flavin-adenine dinucleotide (FAD) in our films showed that rotational

restraint is incomplete. The period of rotation of FMN calculated from its fluorescence polarization in water (0.01) by Weber's method<sup>4</sup> is  $10^{-8}$ – $10^{-9}$  sec. Low polarizations were also measured when FMN, FAD, rose bengal and eosin were dissolved in concentrated aqueous solutions of methyl cellulose which had macroscopic viscosities comparable with glycerol (Table 1). Even in films dried over calcium chloride for 12 h complete rigidity was not observed, the polarization of FMN rising to 0.31 (Table 2). This is well below the value of 0.43 which is measured for a solution of FMN in glycerol.

Table 1

(a) FLUORESCENCE POLARIZATIONS IN AQUEOUS METHYL CELLULOSE SOLUTIONS

Methyl cellulose concentration (g/l.)	FMN	Fluorescence polarization FAD	Eosin	Rose bengal
0	0.014	0.024	0.075	0.142
3.26	0.017	0.029	0.114	
6.41	0.015		0.145	
9.62	0.020	0.034	0.162	
12.83	0.022		0.177	
17.66	0.025	0.043	0.189	
22.50	0.029	0.043	0.195	0.204

(viscosity = 5.5 poise)

(b) FLUORESCENCE POLARIZATIONS OF FMN IN WATER/GLYCEROL MIXTURES

Viscosity of water/glycerol mixture (in poise)	Fluorescence polarization
10	0.430
6.6	0.392
4.6	0.384

Table 2. FLUORESCENCE POLARIZATIONS OF FMN IN METHYL CELLULOSE FILMS

Optical density of FMN	Fluorescence polarization
0.2	0.28
0.2*	0.31
0.2†	0.25
0.2*†	0.28
0.5	0.29
~5.0	0.25
~10.0	0.20

\* These films were dried for 12 h over calcium chloride.

† These films were made from solutions of methyl cellulose concentration half that normally used.

The low polarizations in methyl cellulose solutions and films might have been caused by light scattering from the methyl cellulose or energy transfer between chromophores. The emitted light is observed at 90° to the exciting beam which necessitates the use of an angled sample position for solids. This does not affect polarization values by more than 15 per cent as was found by studying a solution in the angled and normal positions. Depolarization by light scattering was shown to be unimportant in two sets of experiments: (a) FMN polarization in glycerol was only lowered by 10 per cent in the presence of solid 'Sephadex' which scattered far more light than a methyl cellulose film, and (b) the fluorescence polarization of the flavo-protein lipoyl dehydrogenase (molecular weight 10<sup>6</sup>) is 0.43 in both water and a concentrated aqueous solution of methyl cellulose. The result of (b) also means that depolarization by energy transfer is unlikely. For a given concentration of FMN the fluorescence in films made from solutions of different concentrations of methyl cellulose differs (Table 2). The more concentrated solutions give films with higher polarizations, which is compatible with depolarization by molecular rotation of the chromophore but not with energy transfer, although this does occur at high FMN concentration (see later).

Fig. 1. Photoreductions of flavins in methyl cellulose films. ○, FMN alone; ×, FMN + EDTA; □, FMN + EDTA + serotonin; △, lumi-flavin alone.

These results suggest that the microscopic viscosities of concentrated methyl cellulose solutions and films are considerably lower than the macroscopic viscosities (compare Tables 1 and 2). Thus we picture both as having channels or cavities in which chromophores (and probably water too) are constrained, but within which they have certain freedom of movement. The observations that oxygen has no effect on the photoreductions (see later) and that when FMN is inhomogeneously distributed in concentrated aqueous methyl cellulose homogeneity is not achieved after several hours support the assumption that diffusion processes in a film are slow. The small changes in the absorption spectrum of FMN in a film, and the fact

that the fluorescence intensity of FAD is unchanged in the presence of methyl cellulose, are evidence that the chromophore is in a largely aqueous environment<sup>5</sup>.

**Photochemistry.** In anaerobic aqueous solutions FMN is photobleached in the absence of external reducing agents, and photoreduced in the presence of ethylenediamine tetraacetic acid (EDTA) and methionine<sup>1</sup>. These reactions also occur in methyl cellulose films (Fig. 1) though no precautions to exclude oxygen are necessary. The films were not inert during these reactions as lumi-flavin (6,7,9-trimethylisoalloxazine), which is not photobleached in solution by the light intensity used, reacted in methyl cellulose. In the photobleaching of FMN hydrogen is abstracted from the ribitol side chain<sup>6,7</sup>, so methyl cellulose can probably donate hydrogen in a similar fashion. The photoreductions in films resemble those in solution in susceptibility to the action of inhibitors<sup>8</sup> (Fig. 1).

Fig. 2. Action spectrum for the photoreduction of FMN in a methyl cellulose film.

Because of the ready reactivity of flavins and the reduction of diffusion problems in films, we have been able to study action spectra for photoreduction. Using the monochromatic exciting light of the spectrofluorimeter to induce reaction, progress was followed by the fall in intensity of flavin fluorescence. The action spectrum has the same shape as the absorption spectrum (Fig. 2),

Table 3. SPECTRAL PROPERTIES OF THE DERIVATIVES CHOSEN FOR MIXED FILM EXPERIMENTS

Derivative	D	A
Visible absorption maximum		
(a) In solution	445 mμ	470 mμ
(b) In a methyl cellulose film	445 mμ	475 mμ
Fluorescence maximum		
(a) In solution	505 mμ	540 mμ
(b) In a methyl cellulose film	530 mμ	570 mμ

Fig. 3. Fluorescence emission spectra of pure and mixed flavin derivatives in a methyl cellulose film. —, *D* alone; ····, *A* alone and 1:1 *A*:*D*.

confirming that the quantum yield of reaction is independent of the wavelength responsible for the excitation.

**Energy transfer.** Energy transfer is most likely when the emission spectrum of the donor overlaps the absorption spectrum of the acceptor<sup>9</sup>. This situation can be realized by using the two flavin derivatives the formulae and spectral properties of which are shown in Table 3. No energy transfer can be observed between the flavins in dilute solutions. In mixed films the absorption spectra are additive, but the fluorescence emissions are not. A little *A* (20 per cent or more total flavin) completely quenches the fluorescence emission of *D* (Fig. 3). In a 4:1 (*D*:*A*) film the reductions of exciting and emitted light (at 530 mμ) as a result of absorption by *A* are about 15 per cent and 10 per cent, respectively, for excitation at 350 mμ. This alone cannot explain the fluorescence quenching of *D*, which suggests that a singlet-singlet energy transfer from *D* to *A* occurs.

Using Förster's formula<sup>9</sup> the mean intermolecular distance at which energy transfer from an excited singlet is as likely as deactivation by other processes ( $R_0$ ) can be calculated. Assuming that the quantum yields of fluorescence in films are the same as those measured in solution (Wentworth, S., and Radda, G. K., unpublished results), critical transfer distances for FMN alone and for a mixture of *A* and *D* are 14 and 21 Å, respectively. The average intermolecular distance in a mixed film of optical density 1.5 is 30 Å, and for FMN alone with an optical density of 0.5 the distance is 45 Å. At very high concentrations of FMN depolarizations greater than 15 per cent have been measured (Table 2). Under these conditions the intermolecular distance is 20–25 Å. The fluorescence polarization of *A* in a film (optical density 0.55 at 475 mμ) is also reduced in the presence of *D* by 15 per cent for excitation at 450 mμ. Thus it appears that energy transfer can be detected for mean intermolecular distances about 50 per cent greater than the calculated  $R_0$  values. This divergence could be caused by our assumption that the refractive index of a methyl cellulose film is 1.33. Nonetheless, energy transfer occurs in far more dilute mixtures of *A* and *D* than are required to observe it for FMN alone, which is in qualitative agreement with calculations. The observation that polarization is constant for low concentrations of FMN in films shows that energy transfer depolarization is not occurring (Table 2).

It is clear that methyl cellulose films not only provide a simple system in which the photochemical properties of flavins and other dyes can be studied, but also offer environments which may be closer than homogeneous aqueous solutions to the natural ones.

## Antibodies of the ABO System and the Metabolism of Human Spermatozoa

by

D. R. ACKERMAN

Center for Research in Reproductive Biology,  
Department of Obstetrics and Gynecology,  
University of Michigan Medical Center,  
Ann Arbor, Michigan

Antibodies of the ABO system can affect the metabolism of human spermatozoa. The main effect is that the anaerobic glycolysis of sperm from men with A or AB secretor phenotypes is lowered in anti-A or anti-B antisera. Respiration, on the other hand, is increased

HUMAN spermatozoa can respire in the aerobic condition, and are also capable of anaerobic glycolysis. It is agreed that glycolysis, aerobic and anaerobic, is quantitatively more important than oxidative function. It was questioned for some time whether human spermatozoa were indeed capable of oxidative reactions or respiration<sup>1-3</sup>. Although at least one earlier worker<sup>4</sup> reported measurable respiration (oxygen uptake), the demonstration was not entirely convincing until the work of Turner<sup>5,6</sup>. Despite the predominance of glycolytic metabolism, it is possible that respiratory function is important *in vivo*, where ejaculated spermatozoa might most efficiently utilize oxidizable intermediates such as lactate<sup>5</sup>.

Many students of mammalian semen consider that the metabolic activity of spermatozoa is correlated with their

fertilizing capacity. In particular, anaerobic fructolysis—production of lactic acid with fructose as the reducing sugar—has been related to number and motility of human spermatozoa<sup>7,8</sup>. Sakakura has found no relation between the number of motile spermatozoa and the production of lactic acid, at concentrations greater than 10 million spermatozoa per c.c. (ref. 9). In many species, respiratory activity is related to spermatozoan motility and concentration<sup>10</sup>.

The subject of this study is the effect of incubation with antibodies of the ABO system on the metabolism of human spermatozoa. It is clear that spermatozoa of secretor-type individuals will absorb specific antibody<sup>11,12</sup>, and there is evidence to suggest that the spermatozoa of non-secretor individuals may also do so<sup>13,14</sup>. Fertility

differentials for matings which are incompatible in the ABO system<sup>16-18</sup> and distorted genotypic ratios in the offspring of such matings<sup>19</sup> may be partly the result of prezygotic selection exercised by antibodies in the reproductive tract. On this assumption, the adsorption of antibody may in some way impair the physiological function of the affected spermatozoa.

Since there is reason to believe that there is a relationship between the fertilizing potential of spermatozoa and their metabolic activity, it was supposed that the influence of ABO antibodies on gametes may be revealed by gross metabolic studies. The metabolic apparatus of mammalian spermatozoa is located in the midpiece and tail; in human spermatozoa, succinic dehydrogenase activity has been found in the midpiece and, to a much lesser extent, in the head<sup>20</sup>. The localization of the antigens of the ABO system on spermatozoa is not known, but antigen should be ubiquitous for secretor donors<sup>21</sup>. For non-secretors there is nothing to be said; it is possible that antigen, if it does exist, may be generally distributed and present at localities on the spermatozoa concerned with metabolic activity. Spermatozoa of non-secretor donors, when incubated with specific ABO antibody conjugated with isothiocyanate, show fluorescence on head and on midpiece and tail<sup>22</sup>.

### Materials and Methods

(1) *Apparatus*. The metabolic studies were carried out with a Warburg rotary apparatus, using micro-Warburg vessels with centre well and single sidearm. Vessels and manometers were calibrated and vessel constants computed by standard methods<sup>21,22</sup>. A thermobarometer was used in each experiment to compensate for local variations of atmospheric pressure.

(2) The concentration of sperm in all specimens of semen was normal or greater than normal. Volume and morphology were normal. The fertility of most donors was established. No attempt was made to use the same concentration of spermatozoa in the different experiments, but variations did not affect experimental results.

(3) *Antisera*. In most cases, commercial immune antisera, diluted with bovine albumin, were used. These were group A, anti-B, and group B, anti-A. Alternatively, undiluted samples of serum from the blood bank of the University of Michigan Medical Center were used, in which cases it was not determined whether the sera contained immune or naturally occurring antibodies; these sera contained the aforementioned types as well as group O, anti-AB.

(4) *Diluents*. Two types of diluent were used. In measurements of respiratory activity, spermatozoa were suspended in Mann-Ringer phosphate (pH 7.8) and in measurements of anaerobic fructolysis the suspending medium was Mann-Ringer fructose phosphate (pH 7.6) (ref. 10). The diluents were not sterile but were replaced periodically to avoid contamination.

(5) *Procedure*. Only one semen specimen was studied at a time. Immediately after liquefaction, the specimen was divided into two parts in proportions determined by the numbers of vessels to be used for respiration measurements and for fructolysis. Each part was washed once in the appropriate diluent for 10 min at 2,500 r.p.m., so as to separate the spermatozoa from the seminal plasma. The spermatozoa were then resuspended in the appropriate diluent.

Six reaction vessels were usually used: two were used for measuring respiration, the sidearm of one containing anti-A and that of the other anti-B. The centre well of each contained 0.5 ml. 10 per cent potassium hydroxide. Two sets of two were used to measure fructolysis anaerobically. In each set, 1.5 ml. of the same antiserum was pipetted into each sidearm, but the centre well of one contained 0.5 ml. 10 per cent potassium hydroxide and that of the other did not.

The appropriate suspension of spermatozoa was pipetted into each vessel to a volume of 1.5 ml. The volume of antiserum in each sidearm was 1.5 ml. The flasks were calibrated for a liquid phase of 3.0 ml. Filter paper folded accordion-wise was inserted into each centre well containing potassium hydroxide to provide sufficient surface for the absorption of carbon dioxide. The vessels were connected to manometers placed in the Warburg water bath, which was maintained at 37° C. The vessels for anaerobic measurements were then gassed for 10 min with pure nitrogen. After the vessels had equilibrated for 15 min, the antisera in the sidearms were tipped into the flasks. Measurements then were recorded every 15 min for 4 h.

### Results

The consumption of oxygen, or the production of lactic acid as measured by displacement of carbon dioxide from the diluent<sup>1</sup>, was computed for each hour<sup>23</sup>, and the results were expressed in  $\mu$ l. per  $10^6$  spermatozoa per hour.

These results were analysed by the covariance method and the number of  $\mu$ l. of gas produced or consumed was taken as the dependent variable. Covariance analysis allows (a) determination of the significance of each regression, (b) comparison of the slopes of the regressions, and (c) testing of the adjusted means of the regressions.

The respiration of sperm from group A secretors is increased in both antisera, compared with that in normal serum. There is significant heterogeneity among the adjusted means ( $F = 4.22^*$ ,  $df = 2,36$ ); the less sensitive method of planned comparisons between means did not, however, allow us to determine the source of this heterogeneity. Glycolysis in these sperm is significantly inhibited by both antisera ( $F = 7.15^{**}$ ,  $df = 2,48$ ).

Neither anti-A nor anti-B had any effect on either respiration ( $F = 1.57$ ,  $df = 2,32$ ) or glycolysis ( $F = 3.02$ ,  $df = 2,24$ ) in sperm from group B non-secretors. Covariance analysis shows significant heterogeneity among the adjusted means of respiration in sperm from group O secretors ( $F = 23.31^{***}$ ,  $df = 2,20$ ). The source of this heterogeneity is the influence of anti-A—the difference between anti-A and normal serum means being  $0.56 \pm 0.19 \mu$ l.\*; anti-B has no effect. There was no effect on glycolysis in these sperm.

In the case of sperm from group O non-secretors, neither respiration ( $F = 2.27$ ,  $df = 2,12$ ) nor glycolysis ( $F = 2.26$ ,  $df = 2,16$ ) was affected by either antiserum.

Comparison of within and regression mean squares for the results on the respiration of sperm from group AB secretors shows that the regressions of volume on time are not parallel: the covariance analysis is therefore not appropriate. In this case, adjusted means were computed for each dependent variable,  $y$ . A value of  $y$ , extrapolated to zero time,  $E(y_0)$ , was taken in order to allow comparisons between means free from the effects of the independent variable:  $E(y_0) = \bar{y} + b(x_0 - \bar{x})$ . The normal deviate for each combination of pairs was computed in order to compare these adjusted means

$$\text{Normal deviate} = \frac{E(y_{0A}) - E(y_{0B})}{\sqrt{(\sigma_A^2 + \sigma_B^2)}}$$

Neither antiserum had any effect on the respiration of these cells.

Covariance analysis showed no heterogeneity among means for glycolysis in these sperm. The adjusted means for glycolysis in both antisera were, however, remarkably depressed compared with normal serum values. As  $N$  was small in this case, the values for anti-A and anti-B were pooled and compared with those for normal serum ( $t = 3.00^{**}$ ,  $df = 18$ ). On this basis, glycolytic inhibition in anti-A and anti-B is taken to be significant.

The respiration of sperm from group AB non-secretors was not affected by anti-A, but was significantly enhanced in the presence of anti-B ( $F = 4.20^*$ ,  $df = 2,20$ ). Differ-

ences between anti-B and normal serum were  $0.08 \pm 0.06 \mu\text{l.}^*$ . Incubation with either antiserum had no effect on glycolysis in these cells.

Before proceeding to a discussion of these findings, the values for oxygen consumption and carbon dioxide production can be compared with those achieved by other workers using manometric techniques. Shettles<sup>4</sup> measured the oxygen consumption of spermatozoa in undiluted whole semen in the Warburg apparatus. He recorded values on fresh specimens of approximately  $0.14 \mu\text{l./h/10}^6$  cells. Only one experiment in the present series is comparable. Type AB spermatozoa in seminal plasma with 0.6 ml. Mann-Ringer-phosphate, with an equal volume of anti-A and anti-B, give an average oxygen consumption of  $0.42 \mu\text{l./h/10}^6$  cells. Most measurements were taken on spermatozoa free from seminal plasma, suspended in Mann-Ringer-phosphate, with an equal volume of antiserum. Under these conditions values were around  $0.125 \mu\text{l./h/10}^6$  cells. Type AB spermatozoa free from plasma in Mann-Ringer-phosphate gave a value of  $0.075 \mu\text{l./h/10}^6$  cells. One could conclude from these results that the contribution to respiration by serum is about 7 per cent of the total, and that of seminal plasma about 83 per cent, while the basic respiration of isolated cells is about 10 per cent of the total. There is internal consistency in these results as it is known<sup>10</sup> that absorption of oxygen by human semen is predominantly associated with the seminal plasma. The discrepancy between the figures of  $0.42 \mu\text{l./h/10}^6$  cells and  $0.14 \mu\text{l./h/10}^6$  cells<sup>4</sup> can be accounted for at least in part by the dilution of the former specimens with serum and phosphate buffer. Turner<sup>5</sup> attempted to measure respiration in human spermatozoa washed and suspended in Krebs saline, by manometric means, and obtained no readings.

Carbon dioxide production in the anaerobic condition (95 per cent nitrogen; 5 per cent carbon dioxide) has been measured on two occasions by the Warburg technique<sup>1,3</sup>. The spermatozoa in each case were free of seminal plasma and resuspended in Ringer solution. The average values were 0.1 and  $0.25 \mu\text{l./h/10}^6$  cells. In the present series, the following approximate average values were obtained: washed spermatozoa in Mann-Ringer-

Fig. 1. Oxygen consumption. Solid lines indicate oxygen consumption of sperm from secretor donors; broken lines indicate that of sperm from non-secretor donors. In the description of each curve, the blood group of the donors is given first, followed by the designation of the antiserum in which the sperm were incubated.

Fig. 2. Carbon dioxide production. Solid lines indicate carbon dioxide production of sperm from secretor donors; broken lines indicate that of sperm from non-secretor donors. In the description of each curve, the blood group of the donors is given first, followed by the designation of the antiserum in which the sperm were incubated.

fructose-phosphate,  $0.03 \mu\text{l./h/10}^6$  cells; in normal serum,  $0.45 \mu\text{l./h/10}^6$  cells; in antiserum,  $0.15$ – $0.25 \mu\text{l./h/10}^6$  cells; spermatozoa in antiserum, seminal plasma and 0.6 ml. fructose-phosphate,  $0.34 \mu\text{l./h/10}^6$  cells. With the exception of the first, these results are comparable with those of MacLeod. The value of  $0.03 \mu\text{l.}$  for spermatozoa in fructose-phosphate is lower by several orders of magnitude than that of MacLeod for roughly similar conditions. This may, in part, be accounted for by three factors: (a) MacLeod's use of 200 mg per cent glucose in his suspensions, as opposed to the use of 5 mg per cent fructose in the present experiment; (b) an initial deficiency of carbon dioxide in both gas and liquid phases in the present experiment compared with those of MacLeod; (c) individual variability; that is, MacLeod's result is an average of more than twenty-five experiments, while we have only carried out a single experiment of this type. In addition, MacLeod<sup>3</sup> apparently pooled the spermatozoa of several donors to minimize variability between specimens.

Four conclusions can be drawn from the observations reported here. (a) Specificity of antiserum in the ABO system has no effect on respiration or anaerobic glycolysis of human spermatozoa from donors of either secretor status. (b) There is a tendency for respiration in sperm of all types to be enhanced in any antiserum, but oxygen consumption is significantly elevated in only four of the twelve combinations tested. In three of these four cases, spermatozoa were those of secretor donors. (c) Anaerobic glycolysis is significantly lower in either antiserum than in normal serum for spermatozoa from secretors of A or AB phenotypes. (d) Anaerobic glycolysis in spermatozoa from non-secretors does not differ from that of the same cells in normal serum.

Thus the only consistent determinant of differential metabolic performance of cells under these experimental conditions is the secretor status of the semen donor. Secreted red blood cell antigen and the presence of any

antibody interact to reduce glycolytic function. Concomitant with the glycolytic depression, there is apparently some tendency to increased respiratory activity. This suggests that the interaction of antigen and antibody tends to force a change-over, in the affected cells, from the primary glycolytic metabolic pathway, to the secondary, or oxidative, pathway. Such a change-over might reasonably be expected to decrease the viability of the affected cells, and consequently their fertilizing capacity.

## Haptotaxis and the Mechanism of Cell Motility

by

S. B. CARTER

Research Department,  
Pharmaceuticals Division,  
Imperial Chemical Industries Limited,  
Alderley Park, Macclesfield, Cheshire

Dr. Carter puts forward a hypothesis for the basis of tissue cell motility involving considerations of thermodynamics. He uses it to explain experimental haptotaxis and other features of cell motility such as ruffling and circus movement. Dr. Moilliet shows that the hypothesis is thermodynamically feasible

In a previous article<sup>1</sup> I described the motility of cultured tissue cells on specially prepared surfaces. The cells used in these experiments did not adhere to surfaces of pure cellulose acetate, but adhered readily if the acetate surface was previously coated with evaporated palladium.

By controlling the amount of palladium deposited, it was possible to make a range of surfaces which gave different degrees of cell adhesion. Experiments with these surfaces emphasized the importance of the underlying substrate in determining cell behaviour. For example, "L" cells showed mutual contact inhibition<sup>2</sup> on a surface to which they adhered strongly, but not on one to which their adhesion was relatively weak. Other experiments involved a gradient of progressively increasing metal deposition on a surface of cellulose acetate. Such a surface presents a corresponding gradient of cell to substrate adhesion, and cells were found to move up this adhesion gradient in a highly directional manner. I called this phenomenon "haptotaxis", and suggested that cell movement from a less adherent to a more adherent surface is the dominant principle in tissue cell motility. I indicated how all movements of tissue cells could be interpreted on this basis, and considered particularly how the principle of haptotactic movement could be applied to chemotaxis and to cancer invasion.

The present paper attempts to relate the phenomenon of haptotaxis to the mechanism of cell movement. This is necessary if it is to be established as a general and overriding principle of tissue cell motility.

As in previous experiments, the cells used were mouse fibroblasts (Earle's "L" strain). These were cultured in Eagle's medium<sup>3</sup> (with 8 per cent heat inactivated calf serum), using oil sealed culture chambers<sup>4</sup>. The technique of preparing cellulose acetate films on cover glasses was described in the previous paper<sup>1</sup>.

Tissue cells depend for their motility on attachment to a suitable substrate. True motility involves the displacement of the whole cell in relation to this substrate. In the simplest analysis, the movement of a cell on a solid material such

as glass involves two prime requirements: the leading margin of the cell must move forward, and the trailing margin must follow in the same direction. It is convenient to consider these requirements separately.

*Movement of the leading margin.* A thin film of cellulose acetate on a cover glass can be scraped to expose areas of underlying glass. When the leading margin of a cell moving on the exposed glass meets the edge of the acetate film, forward movement ceases immediately.

This behaviour resembles the "contact inhibition" which occurs when a cell meets another cell moving on glass, and the operative mechanism appears to be the same.

Fig. 1 shows a cell approaching the edge of a film of cellulose acetate, and the same cell shortly after it has made contact with the film. It will be seen that the film completely blocks the forward movement of the cell. If the acetate surface is sufficiently clean, no visible extension takes place over it. The simplest and most satisfying explanation for this effect is that the leading

Fig. 1. A cell on glass approaching the edge of a cellulose acetate film, and the same cell after making contact with this edge. Forward movement of the leading margin of the cell ceases as soon as contact is made. (Phase contrast  $\times 375$ .)

Fig. 2. The leading margin of a cell moving on a surface of alternating strips of cellulose acetate and glass. The margin bulges forward on the lighter (glass) strips, and is held back on the darker (acetate) strips. (Phase contrast  $\times 1,000$ .)

edge of a cell moving on glass extends by passive spread, and not by forces arising inside the cell. The glass provides a wettable surface on which spreading can occur, but the acetate presents a surface which cannot be adequately wetted by the cell. In the same way a drop of water spreading on a glass plate will stop spreading exactly at the edge of a film of grease.

Further evidence for the passive nature of cell extension is provided by the appearance of a cell moving on a substrate consisting of alternate strips of cellulose acetate and glass (Fig. 2). The leading edge of this cell is seen to bulge forward on the lighter glass strips, and to be held back on the darker acetate strips. The same pattern is evident when a drop of gamma-globulin solution (for example) spreads passively on the same type of surface (Fig. 3).

Weiss<sup>5</sup> argues that the expansion of the cell surface at an interface cannot be regarded as a basically passive process. In support of this he cites the finding of Lettré<sup>6</sup> that cells dosed with ATP tend to remain extended instead of rounding up when undergoing mitosis. Even if it were shown that the presence of ATP at or near the cell surface is a necessary requirement for cell extension, this would not exclude the possibility that such extension depends on passive spread. All that is implied by "passive" in this context is that the final process in the movement of the leading edge of the cell involves intermolecular forces acting between the surface of the cell and the surface of the substrate. Metabolically derived energy can be represented in the form of surface free energy as well as any other, and there is no reason why it should not act in this form to bring about cell movement. In fact the terms "active" and "passive" applied to particular processes become meaningless when considered at the molecular level. Nevertheless I think the concept of passive spread (as defined) is valuable in attempting to understand the mechanism of cell movement, provided it is not taken to mean that the cell does not contribute any energy to the process.

The nature of the forces concerned with cell adhesion is poorly understood and largely disputed. Curtis<sup>7</sup> has used interference reflexion microscopy to investigate this problem. He has calculated that the closest approach of the cell surface to a glass substrate is about 100 Å. This type of calculation necessarily involves making a large number of assumptions, but there is also the tacit assumption that this gap is constant in width over an unspecified area of surface. The size of this area depends on the resolving power of the method as a whole, but this cannot be better than the optical resolving power of the microscope. Even at its theoretical minimum, therefore, this area will be very large in relation to a gap of 100 Å. It seems highly unlikely that a macromolecular surface would present a regular contour on this scale.

If a gap of this order does exist, then it cannot strictly be said that the glass is wetted by the cell surface. Nor can the relationship of the two surfaces be considered by reference to a single interfacial or boundary tension. Until these problems are settled, however, it seems preferable to use these terms provisionally, as there is no virtue in introducing new terminology before it can satisfactorily be defined.

The idea that surface tension forces are involved in cell motility is a very old one. In 1886 Berthold<sup>8</sup> interpreted amoeboid movement in terms of local variations in surface tension, and Rhumbler<sup>9</sup> extended these ideas further. Many other workers adopted a similar approach to problems of cell movement. Harvey<sup>10</sup> gives a useful historical summary of this early work.

Theories of cell movement which involve surface tension forces have now become unfashionable. When they are mentioned at all it is usually to exclude them from serious consideration. The older ideas regarded the cell as a drop of protoplasm of which the surface simply represented the outermost exposed layer of this material. The realization that the cell was surrounded by a distinct membrane completely invalidated this earlier concept, but the presence of a membrane does not in any way exempt the cell from the influence of forces due to boundary tensions. Naturally, the membrane will modify the effect of these forces on the cell as a whole, and the properties of the membrane as a physical structure must be taken into account.

Cells can, of course, extend into a liquid medium in the total absence of an extraneous surface. Such extensions are usually small and occur during anaphase "boiling", for example. Free extensions of this type are not in any way incompatible with the idea of passive spread on a surface. Both types of extension can be interpreted as a local reduction in the boundary tension at the cell surface. In the case of a free extension this could be due to local differences in the distribution of a surface active material. In the case of passive spread the wettable surface itself may lower the boundary tension at the point of contact.

*Movement of the trailing edge.* When considering the movement of the trailing edge of the cell, it is helpful to distinguish the situation in which a cell is moving on a gradient of adhesion from that in which it is moving on a uniform surface.

In the case of an adhesion gradient (such as that produced by a graded deposition of palladium on cellulose acetate), the margin of the cell which lies highest on the gradient will be subject to the greatest spreading tension. Correspondingly the opposite margin, on a lower part of the gradient, will be in contact with a less wettable surface and subject to a lower spreading tension. If the gradient

Fig. 3. The margin of a drop of gamma-globulin solution spreading on the same surface as that shown in Fig. 2. The margin of the drop presents the same pattern as the margin of the cell, bulging forward on the glass strips and held back on the strips of cellulose acetate. (Phase contrast  $\times 480$ .)

is sufficiently "steep" and the cohesive forces of the cell sufficiently strong, then the stronger pull on the side of the cell farthest up the gradient might be sufficient to draw the cell bodily up the gradient. In theory at least, the cell could move up such a gradient without expending any metabolic energy, since it will have moved to a position of lower total free energy. In practice, however, with artificial gradients of this type, I think that the energy contributed by the gradient itself represents only part of the energy required to move the cell. This contribution is nevertheless sufficient to determine its direction of movement. For the rest it is necessary to invoke the kind of mechanism which I shall propose for movement on a uniform surface.

Before discussing this mechanism, it may be useful to consider certain aspects of the nature of adhesion. For present purposes adhesion will be considered in terms of relative wettability. When a cell adheres to a glass surface it is commonly described as though the only surfaces involved were those of the cell and the glass. But this is fundamentally a system of three phases in which the cell, the glass, and the fluid medium in which they are immersed all need to be considered equally. This means that the medium/glass interface is not only relevant to the adhesion of the cell: it should be accorded exactly the same importance as the cell/glass interface. Indeed, the adhesion of a cell to a solid surface represents a three way competition, each phase being competed for by the other two. In the argument which follows, however, the consequences of changes at the cell/medium interface will not be considered, and for descriptive purposes the adhesion of the cell will be discussed in an over-simplified form in terms of a competition for the solid surface between the cell and the medium. The concept of a cell failing to adhere because the adhesion forces between it and a particular surface are too weak is incomplete. Adhesion may also fail because the adhesion forces between the medium and this surface are particularly strong. This would enable the medium to displace the cell from contact with it. A drop of oil may spread on a glass surface in air, but the same oil may fail to spread on glass under water because the water can successfully compete with it for the glass surface.

To return to the subject of cell movement on a reasonably uniform surface such as glass, the problem is to account for the fact that the trailing margin of the cell moves in the same direction as its advancing margin. If the movement of the advancing margin is due to passive spread, this spread would be expected to be equal in all directions. In the case of a cell showing directional movement on such a surface, this is clearly not the case, and it is necessary to find a reason for this loss of symmetry.

Using the technique of ellipsometry, Rosenberg<sup>11</sup> has investigated the submicroscopic layer of material which appears to be deposited by cells when in contact with certain substrates such as chromium coated glass. He called this material a "microexudate" and considered that it was transferred directly to the substrate by contact with the cell, since none could be demonstrated in the supernatant from cell suspensions. Chemically it appeared to be a complex of materials including protein. Rosenberg also showed that culture media containing serum very rapidly produced an adsorbed layer of protein on chromed glass. Microexudate also appeared to be deposited on such a protein film when cells were cultured on it, though the rate of deposition was reduced. The probable existence of an adsorbed layer of protein should clearly be borne in mind when considering surfaces in contact with media containing serum, and all the experiments described here were carried out in the presence of serum.

Taylor<sup>12</sup> has investigated the adhesion of cells to a variety of different substrates. He found that the adhesion of cells to glass is greatly reduced if the glass is covered by a layer of microexudate produced by previous contact with cells. The loss of cell adhesion on glass surfaces

"contaminated" by microexudate could be due to a reduction in the affinity of the altered glass for cell surfaces corresponding to an increase in the cell/glass boundary tension. As we have seen, however, an equally possible explanation is that the affinity of the glass for medium has been increased, corresponding to a reduction in the medium/glass boundary tension. In fact this is the more likely explanation, since if the substance responsible for this effect is transferred by direct contact, it is highly improbable that such a transfer could result in an actual increase in the boundary tension between the contacting surfaces.

If a cell margin which is spreading passively outwards on a wettable surface such as glass should be momentarily reversed at a particular point, then a small area of glass which has been contaminated by microexudate (by contact with the cell) would be exposed. If the wettability of the contaminated glass for medium is increased as suggested, this could enable the medium to compete successfully with the cell and displace it from the glass at this point. The reversal of the cell margin which is necessary to initiate this process has only to expose a very small area of altered glass surface. A random Brownian event may well be sufficient for this purpose.

The situation is now no longer symmetrical, and a potential direction of movement has been determined. The medium would be expected to continue to displace the cell from the glass where the contaminated area is exposed, so that this becomes the trailing margin of the cell. The leading margin is now able to advance on uncontaminated glass with improved efficiency. This is because it is relieved of the opposing tension of the opposite cell margin transmitted by the cohesion of the cell. These factors would tend to reinforce each other, so that once the direction of the cell has been randomly determined this direction would tend to be preserved, provided the newly encountered surface is homogeneous and free of the contaminating influence of other cells.

In practice, when a cell is newly seeded on glass, it may be a considerable time before one margin of the cell gains a sufficiently strong advantage over the others to result in directional movement. Many "random" reversals of outward spread may occur before a sufficiently asymmetrical position is established to ensure continuity of movement in a particular direction. Until this position is reached, the cell may undergo many changes of shape and minor shifts of position. In marked contrast to this, directional movement on an adhesion gradient is immediate.

The suggestion that the trailing margin of a cell moves forward because it is displaced by medium may seem an even more "passive" movement than that proposed for the leading edge. Again there is no intention of suggesting that the cell does not provide energy for its own movement. Although no attempt is made here to identify the energy conversions involved, it should be borne in mind that the driving force of the medium would be provided on this theory by the surface active material deposited by the cell. This material would require the expenditure of metabolic energy for its synthesis, and in the process of movement it would need to be continuously replaced.

A basically similar mechanism may be operating to produce the curious phenomenon of circus movement which Holtfreter and others have described for certain embryonic cells<sup>13</sup>. In contact with glass these cells may produce a bleb of cytoplasm which protrudes at one side and proceeds to move round the periphery of the cell. When speeded up by time lapse photography each cell appears to be spinning in a clockwise or anti-clockwise direction. Again the direction of movement of the cytoplasmic bleb may be the consequence of a random event which tips the balance in a particular direction. For reasons already discussed the bleb would be expected to continue round the cell, its leading margin being drawn on by passive spread, and its trailing margin giving way

to the medium as a result of a surface active material deposited in its wake. It is only necessary to postulate that this material is desorbed or otherwise inactivated after an interval of time, so that it is reduced or rendered less effective by the time the bleb has gone full circle. The bleb would then continue to move round the cell indefinitely.

If adhesion is considered in terms of the relative success of the cell in its competition with the medium for contact with the glass, then the mechanism of movement proposed for tissue cells on a homogeneous surface such as glass may also be considered as representing a movement from a surface offering relatively poor adhesion to a surface offering better adhesion. Seen in this way, the movement of the cell on a uniform surface is also an example of haptotactic movement. Indeed, the only distinction between this and movement on a surface representing an adhesion gradient is that the cell is considered to be creating its own adhesion differential as it moves. An important consequence of this is that once the cell is in motion and has established its own adhesion gradient, it may continue across a line dividing two dissimilar surfaces in the "wrong" direction, that is towards the surface offering the lower relative adhesion. This is because the differential generated by the moving cell may represent a greater difference of adhesiveness than that between the two dissimilar surfaces.

*The ruffled membrane.* The picture of cell movement so far presented has taken no account of the ruffled membrane. Ruffling movements of the cell membrane are characteristic of many tissue cells moving on glass, and are well shown by the "L" cell. Ruffling can occur at any margin of the cell in relation to its direction of movement, and it is by no means confined to the leading edge. Nevertheless, there is a tendency in rapidly moving cells for the ruffled membrane to be more fully developed at the front of the cell, and the trailing margin may show no ruffling at all. For this reason it has been suggested<sup>14</sup> that the ruffled membrane may be looked on as the "organ of locomotion" of cells which demonstrate this type of behaviour. This view is widely held, and theories of cell movement<sup>15</sup> have been based on the idea that the ruffles are essentially wave-like in character, and that their rearward movement across the surface of the cell is responsible for the forward movement of the cell as a whole. The formation of a ruffled membrane, however, is dependent on a surface (such as glass) which offers a relatively high degree of adhesion. "L" cells, for example, remain essentially spherical on a surface offering little adhesion (such as cellulose acetate), and do not show any ruffling, yet they are able to move as efficiently as on glass. It is probably misleading, therefore, to regard the ruffled membrane as the organ of locomotion of the cell.

In order to interpret the ruffled membrane, it is first of all necessary to have an accurate picture of the physical pattern which it presents. Even with the help of time lapse cinematography, this pattern is complex and difficult to follow. Cells which have been trypsinized and newly seeded on glass are particularly valuable for investigating the pattern of ruffle formation. In many cases these cells attach and spread out without ruffling. The first ruffles to appear tend to be single and isolated, so that their formation can be observed critically, and a clear sequence of events can be followed. Fig. 4 shows such a cell photographed at intervals against a reference grid. The first photograph shows the cell spreading outwards, presenting the regular circular outline which would be expected for passive spread on a uniform surface. In the second photograph the cell margin has extended further. The cell outline is less regular but there is no true ruffling. The first ruffle appears in the third photograph, and is indicated by a long arrow. Reference to the grid lines shows that the formation of the ruffle is accompanied by a retreat of the cell margin at this point. The ruffle itself appears to be formed by the piling up of cytoplasm as the

Fig. 4. A trypsinized cell, newly seeded on glass and photographed at intervals against a reference grid to illustrate the development of the ruffled membrane. The arrows indicate features mentioned in the text. (Phase contrast  $\times 800$ .)

cell margin moves back. Apart from this initial movement, there is no tendency for the ruffle to be propagated backwards over the surface of the cell. The fourth photograph shows a rounded extension (indicated by a short arrow), reappearing in the same region. This extension will in turn retreat to form another ruffle. This sequence can also be seen in the fully developed ruffled membrane, but its essential simplicity is obscured by the number of ruffling movements which are then superimposed.

This pattern of movement can be interpreted in precisely the same way as I have attempted to interpret the movement of the cell as a whole. Each ruffle represents a retreat of the cell margin in the face of medium which is successfully competing with the cell at that point by virtue of the microexudate deposited by the cell. The re-extension of this margin can occur when this material has become partly desorbed or inactivated, as discussed in relation to circus movement.

Little is known about the way in which additional cell membrane is made available to accommodate new cell extensions. Whatever the mechanism, there must be a limit to the rate at which new membrane can be made available, and this may be an important controlling factor in the rate of cell extension. Ruffling is seen particularly when the cell is well spread, and the cytoplasm may form an extremely thin layer at the front of the cell, except where it is locally thickened as a ruffle. In this situation the local resources for providing new surface membrane to allow further extension may be particularly limited. If these resources become momentarily exhausted, the advancing margin must stop, and at this point the margin may be especially vulnerable to the random thermal factors already discussed which could initiate the reversal of the cell margin. The reversal itself would be checked by the development of tension in this part of the membrane as a result of the movement of other parts of the margin which are still making forward progress.

If this is a basically correct interpretation of ruffle formation, then, far from representing the organ of locomotion of the cell, the ruffling of the membrane actually impedes the progress of the cell. This is because each ruffle may be regarded as a temporary set-back to the forward movement of the leading cell margin.

In so far as ruffling may reflect the principles which determine cell movement, however, the detailed study of ruffle formation is highly relevant to the investiga-

tion of cell motility. In this context, the behaviour of recently trypsinized cells may be of particular value. Superficially, the failure of such cells to show ruffling movements until they have fully recovered from their exposure to trypsin suggests that this enzyme may destroy some component of microexudate on which ruffling may depend, or that it interferes in some way with microexudate production. Rosenberg<sup>11</sup> has presented evidence that trypsin adsorbed to the cell surface may continue to be active in this way.

It is still necessary to explain the relative or total lack of ruffling at the trailing margin of the cell.

Since the interpretation of ruffle formation previously discussed involves the alternate spreading and retreating of a thin layer of cytoplasm, it depends for its continuation on the continued ability of the cell margin to extend. The surface relationships of the cell membrane at the trailing margin do not favour extension, and the general state of tension in the membrane in this region (as evidenced for example by the tautness of the cytoplasmic strands which are often dragged behind the cell during its progress) also militates against the local expansion of the membrane which extension must involve. It is noticeable that should this tension be generally or locally relieved by a change in cell direction, for example, ruffling at the trailing margin is resumed. When a cell on glass meets the edge of an acetate film, or demonstrates "contact inhibition" on meeting another cell, there is also a tendency for ruffling to be reduced or cease at the contacting margins. This could again be because the initial extension on which the formation of a ruffle depends is now restricted.

Although the mechanism of cell movement here proposed is basically very simple, a more complete interpretation along these lines becomes extremely complex. This is particularly true if the potential influence of the boundary tension between the inner surface of the cell membrane and the cytoplasm is taken into account<sup>16</sup>. Each situation demands the consideration of a number of factors which may sometimes oppose, and sometimes support, each other. In addition it will seldom be clear in a given instance which are the main factors concerned and which make only minor contributions. A local feature of a moving cell may have an essentially local explanation, but it is also liable to be influenced by situations obtaining elsewhere in the cell. In assessing the relative importance of these factors, it would be extremely useful to know, for example, to what extent the forces due to a spreading tension at one margin of the cell may be transmitted to another part of the cell by tension in the cell membrane. This problem would be complex enough if the cell membrane were a stable structure, but the fact that it may be in a dynamic state, involving the continuous interchange of material between the membrane and the cell interior, could make its formal solution virtually impossible.

The theory of cell movement I have put forward does not invoke any internal mechanisms for moving the cell, such as specialized contractile elements. If such mechanisms can be shown to exist in a particular type of cell, they must clearly be taken into account. Apart from this, the theory is intended as a general basis for the motility of all types of tissue cell. On the other hand it is not intended to apply in this form to the mechanism of "true" amoeboid movement such as that shown by *Amoeba proteus*.

The purpose of investigating the movement of tissue cells *in vitro* is to try to identify the principles which govern their motility, in the hope that these principles may also be applied to such cells in their normal environment *in vivo*. Extrapolation of *in vitro* results in this way is a hazardous but necessary step. In attempting to transfer these ideas to their proper context in the living animal, an important question is raised: to what extent may the movement of a particular cell be due to "pre-

existing" gradients of surface adhesion presented to it, and to what extent could it be due to a gradient of the cell's own making? If it is mainly a question of pre-existing adhesion differentials which are presented to the cell, then a rather disturbing possibility has to be entertained—that cell movement on artificial materials such as glass may be dependent on a mechanism which is largely irrelevant to cell movement *in vivo*.

I thank Dr. J. L. Moiliet for valuable discussions on surface thermodynamics, and Miss Janet Way for technical assistance.

### Elementary Surface Thermodynamics of Carter's Theory of Haptotactic Cell Movement

THE mechanism of haptotactic cell movement proposed by Carter<sup>1,2</sup> can readily be shown to be feasible in terms of the thermodynamics of surfaces, provided that the inner and outer surfaces of the cell membrane can be treated as interfaces with positive boundary tensions. The simplest case is represented in Fig. 1, which shows the cross-section of a cell, represented as a droplet of liquid (2), on the surface of a solid substrate (3), in competition with another liquid (1). Suppose now that  $\gamma_{13}^x$ , the value of the interfacial tension (1)-(3) at  $X$ , is less than the value  $\gamma_{13}^y$  at  $Y$ . As Carter has pointed out, this could be due to a surface free energy gradient on the surface of the solid, produced for example by differential metal shadowing. Alternatively, or perhaps at the same time, a surface-active material might be adsorbed or deposited at the (2)-(3) interface and the droplet slightly displaced by accident to the left, leaving a "contaminated" (1)-(3) interface of lower interfacial tension immediately to the right of  $Y$ .

Fig. 1.

The net spreading tensions at  $X$  and  $Y$  are given respectively by

$$t_x = \gamma_{13}^x - \gamma_{23}^x - \gamma_{12}^x \cos \theta_a \quad (\text{to the left})$$

$$\text{and } t_y = \gamma_{13}^y - \gamma_{23}^y - \gamma_{12}^y \cos \theta_r \quad (\text{to the right})$$

the resultant tension (to the left) being

$$t = t_x - t_y = (\gamma_{13}^x - \gamma_{13}^y) - (\gamma_{23}^x - \gamma_{23}^y) - (\gamma_{12}^x \cos \theta_a - \gamma_{12}^y \cos \theta_r) \\ = \Delta\gamma_{13} - \Delta\gamma_{23} - (\gamma_{12}^x \cos \theta_a - \gamma_{12}^y \cos \theta_r) \quad (1)$$

$\theta_a$  and  $\theta_r$  not necessarily being equilibrium contact angles.

It is such a possible condition that the values of the  $\gamma$ 's be such that  $t$  is greater than zero. On a differentially

shadowed surface, for example,  $\gamma_{12}^x$  and  $\gamma_{12}^y$  would probably be equal, but  $\Delta\gamma_{13}$  could be larger than  $\Delta\gamma_{23}$ , especially if the (2)-(3) boundary tensions were in general lower than the (1)-(3) tensions. To take a second case, if  $\Delta\gamma_{13}$  is positive because of contamination of the (1)-(3) interface to the right of  $Y$  by materials from the cell  $\Delta\gamma_{23}$  would be zero and  $\gamma_{12}^x = \gamma_{12}^y$ , except in so far as movement of the cell disturbed the adsorption equilibria at  $X$  and  $Y$ . In either or both of these possible cases,  $t$  would be zero only if  $\cos \theta_a > \cos \theta_r$ , but this would destroy the symmetry of the drop, the radii of curvature of the (1)-(2) interface becoming smaller near  $Y$  than near  $X$ . This dissymmetry would cause a pressure to the left, which would prevent the differences in the two contact angles from becoming large enough to reduce  $t$  to zero. (For the simple case just mentioned, that  $\Delta\gamma_{23} = 0$  and  $\gamma_{12}^x = \gamma_{12}^y$ ,  $t$  would become zero only if  $\cos \theta_a = \cos \theta_r + \Delta\gamma_{13}/\gamma_{12}$ , but the pressure due to the dissymmetry would cause  $\cos \theta_a$  to lie between this value and  $\cos \theta_a = \cos \theta_r$ .)

The kinetics of the proposed mechanism of haptotaxis, which involves the kinetics of adsorption processes at the various interfaces, as well as viscous and frictional effects, are obviously very complicated. These effects are not considered in the present treatment, which suggests only that a mechanism based on boundary tension effects is thermodynamically possible. The energy for the process, on this picture, would of course come from a decrease in the total free energy of the system. On a differentially shadowed surface, for example, a contribution to this decrease would come from a movement of the cell towards a position of lower total surface free energy; on the hypothesis of a lowering of  $\gamma_{13}$  near  $Y$  by adsorbed material, the energy would come from the total free energy of adsorption of this material.

The present treatment can be extended to the true situation, in which the cell is enclosed in a membrane. Suppose that the droplet in Fig. 1 contains a third liquid phase (4), which has exactly the same shape as the droplet, leaving a "membrane" layer of (2), which is so thin as to occupy a negligible fraction of the total volume of the droplet, but is thick enough to have an internal boundary tension  $\gamma_{24}$ . We also assume that this very thin layer is kept in place by a structure of some sort, but that this structure does not interfere significantly with the effects of the boundary tensions  $\gamma_{12}$ ,  $\gamma_{23}$ , and  $\gamma_{24}$ . It can be shown

in such a case that the contact angle (measured inside the composite droplet) is given under equilibrium conditions by

$$\cos \theta' = \frac{\gamma_{13} - \gamma_{23} - \gamma_{24}}{\gamma_{12} + \gamma_{24}} \quad (2)$$

(This expression can be derived in an analogous manner to Young's equation, for example by finding the dimensions of the composite droplet which corresponds to a minimum in the total free energy of the system, at constant temperature, pressure, and composition.) Similarly, the net spreading tension will be given in this case by

$$t' = \Delta\gamma_{13} - \Delta\gamma_{23} - \Delta\gamma_{24} - [(\gamma_{12}^x + \gamma_{24}) \cos \theta'_a - (\gamma_{12}^y + \gamma_{24}) \cos \theta'_r] \quad (3)$$

where  $\theta'_a$  and  $\theta'_r$  are the prevailing contact angles (not necessarily equilibrium ones) obtaining at  $X$  and  $Y$ , respectively. The same general argument applies as before for the case that  $\Delta\gamma_{13} > 0$ , taking account of the appearance of  $\gamma_{24}$  in equation 3, and again leads to the conclusion that it is possible for  $t$  to exceed zero. Several points of special interest are, however, worth noting.

(a) It follows from equation 2 that, since  $\gamma_{24}$  is positive, each  $\cos \theta'$  will be smaller than the corresponding  $\cos \theta$ , other boundary tensions being unaltered; that is, the general effect of the presence of the internal interface is to increase the contact angle.

(b) The kinetics of adsorption will obviously be even more complicated for the case of a composite droplet.

(c) Fluctuations in the shape of the (2)-(4) interface, and local fluctuations in the value of  $\gamma_{24}$ , could contribute to the "ruffling" of the cell membrane which is frequently observed in motile tissue cells. If, for example, the (2)-(4) interface near  $X$  oscillated between the shape shown in the diagram and a rounded-off shape as the drop advanced, a fluctuation would be imposed upon  $\theta'_a$ , and ripples would be generated along the double boundary between phase (1) and the interior of the cell.

## Effects of Cytochalasins on Mammalian Cells

by

S. B. CARTER

Research Department, Pharmaceuticals Division,  
Imperial Chemical Industries Limited,  
Alderley Park, Macclesfield, Cheshire

The cytochalasins—a group of mould metabolites—inhibit movement and cytoplasmic cleavage in cultured cells. At higher doses they cause nuclear extrusion which may lead to total enucleation

SEVERAL species of moulds have been found to produce a number of chemically related metabolites which show unusual biological activity. The name "cytochalasin" (Greek *cytos*, a cell; and *chalis*, relaxation) is suggested for this new class of compounds. The name is intended as a general description of the effects which are characteristic of these substances. It is not meant to imply a particular mode of action.

Four cytochalasins have been isolated in these laboratories by Dr. W. B. Turner. These have been designated A, B, C, and D. Cytochalasins A and B were obtained

from culture filtrates of *Helminthosporium dematioides*. Cytochalasins C and D were isolated from *Metarrhizium anisopliae*. Cytochalasin-like activity seems to be widely distributed. Filtrates from nine other species (representing four orders of fungi) have been found to produce similar effects. The four cytochalasins so far isolated show essentially similar activity but differ in potency. Cytochalasins C and D are about ten times as active as cytochalasins A and B.

The experiments described here were carried out with cytochalasin B. This compound has a novel macrolide

Fig. 1. Binucleated "L" cells produced by exposure to cytochalasin B at 1.0 µg/ml. for 24 h ( $\times 250$ ).

structure in which the lactone ring is joined to a bicyclic lactam system. Its molecular structure is reported elsewhere<sup>1</sup>.

Earle's "L" strain of mouse fibroblast was used in most of these experiments. The cells were cultured on glass cover slips using Eagle's medium<sup>2</sup> with 8 per cent inactivated calf serum. For observations on living cells, oil-sealed culture chambers were used<sup>3</sup>. The compound is poorly soluble in water, and appropriate dilutions in culture medium were made from a stock solution in dimethyl sulphoxide (0.1 per cent).

**Prevention of cytoplasmic cleavage.** Cytochalasin B prevents cytoplasmic cleavage at a concentration of 0.5 µg/ml. After 24 h exposure to this concentration, many cells are found to contain two nuclei. At 1 µg/ml., inhibition of cytoplasmic cleavage is virtually complete (Fig. 1). Nuclear division proceeds normally, and following this a deep cleavage furrow may develop. This furrow fails to separate the cells completely, however, and subsequently retreats. If the compound is removed by perfusion with normal medium, the binucleated cells produced undergo multiple cytoplasmic cleavage following the next nuclear division. No compound has previously been described which specifically and consistently prevents cytoplasmic cleavage without interfering with nuclear division. Wolpert has pointed out the potential value of such a compound for investigating the cleavage mechanism<sup>4</sup>.

Cells remain viable for many days in the continuous presence of cytochalasin B. Although the mitotic rate is reduced, many consecutive nuclear divisions may take place without cleavage. Very large multinucleated cells are produced which are clearly visible to the naked eye. All the nuclei in a particular cell appear to enter mitosis synchronously. Synchrony of nuclear division in multinucleated cells is regarded as the rule in a very wide range of biological material. If all the nuclei divide together, it would be expected that the number in each cell would double after each mitotic cycle. In fact this does not happen. More than a hundred individual cells have been followed over a period of 7 days under continuous treatment with cytochalasin B, to investigate the progressive increase in nuclearity which occurs. The usual pattern is for the nuclear complement of each cell to increase one at a time. This is a surprising finding which seems to conflict with an established cytological principle. It may be that synchronous nuclear division in multinucleated cells cannot safely be inferred from fixed preparations in which all the nuclei appear to be in the same mitotic phase. The simplest explanation for the production of only one nucleus per cycle is that a multinucleated cell may enter mitosis when only one of its nuclei is fully prepared and competent to divide. This implies that the other nuclei may be

induced to go through a "pseudomitotic" cycle which closely imitates mitosis, but involves no overall change in the nuclei taking part. Such a cycle could entail chromatin condensation and "chromosome" formation, followed by complete reconstruction of each nucleus in its original form. It is difficult to obtain direct evidence for this explanation because of the large number of chromosomes involved. If it can be shown to occur, however, pseudomitosis would have important implications for the initiation of nuclear division and the mechanism of chromosome formation.

**Inhibition of cell motility.** Time lapse cinematography reveals that "L" cells stop moving when the culture is perfused with cytochalasin B at 0.5 µg/ml. The effect is immediate and is reversed with equal rapidity when normal medium is restored. Treated cells remain in the same position for many days. This greatly facilitates the long term investigation of nuclear changes by time lapse techniques.

Ruffling of the cell margin is also inhibited. Ruffle formation is resumed as soon as the compound is removed.

No effect has been observed on the motility of a number of fresh water ciliates and flagellates even at doses as high as 50 µg/ml. Similarly the motility of mouse spermatozoa was unimpaired at this concentration.

**Extrusion of nuclei.** Nuclear extrusion is occasionally observed in "L" cells exposed to cytochalasin B at 1 µg/ml. At a dose of 10 µg/ml., however, a high proportion of cells extrude their nuclei (Figs. 2 and 3).

The initial stages of this process are dramatically rapid. Within minutes the nucleus has formed a prominent bulge in the cell membrane. This bulge progresses rapidly

Fig. 2. Living "L" cells before exposure to cytochalasin B. (Phase contrast  $\times 350$ .)

Fig. 3. The same field as Fig. 2 showing nuclear extrusion 1 h after exposure to cytochalasin B at 10 µg/ml. (Phase contrast  $\times 350$ .)

until the nucleus appears to be entirely outside the cell, but still attached by a delicate cytoplasmic thread. At this stage the process can be reversed by washing with fresh medium. The nucleus is drawn back into the cell and is functionally unimpaired. If the nucleus is allowed to remain fully extruded for several hours, irreversible damage may be done and the nucleus becomes pycnotic.

The thin thread connecting nucleus and cytoplasm becomes progressively longer and more attenuated. It can easily be severed with a micromanipulator needle. Spontaneous enucleation also occurs, and many cells can be found without nuclei after exposure to the compound for 24 h. The mechanism later proposed for nuclear extrusion does not account for the complete expulsion of the nucleus. When this occurs it may be dependent on loss of nuclear viability or accidental rupture of the connecting thread. Cells which have lost their nuclei in this way have been found to be viable 24 h later, but no detailed investigation of their ultimate fate has been attempted. Such cells are capable of limited movement if placed in normal medium.

**Mechanism of action.** Cells which have been exposed to cytochalasin *B* at 0.5 µg/ml. are flatter than untreated cells, and each cell occupies a proportionately larger area of glass surface. The cell outline tends to be relatively simple and approximates to a circular shape. This appearance suggests that adhesion between the cell and the glass may be increased. This could indicate that the compound is adsorbed at the cell/glass interface, lowering the interfacial tension between them. Cell adhesion to glass may be regarded as a three way competition for mutual contact between cell, glass and culture medium. It should be kept in mind, therefore, that a reduction in cell/medium boundary tension, or an increase in glass/medium boundary tension, could have the same effect. These possibilities are not mutually exclusive.

Cells which have been dosed with cytochalasin *B* in suspension adhere to a glass surface very much more rapidly than untreated cells. After attachment, however, their rate of spreading is less than that of control cultures. This could mean that adsorption of the compound on the cell surface also increases its surface viscosity.

Cytochalasins *C* and *D* completely prevent cell cleavage at 0.05 µg/ml. A mould filtrate at present under investigation appears to contain an even more active metabolite. Crude extracts of this filtrate have shown cytochalasin-like activity at a dilution of 1/20,000,000. The high potency of these compounds is associated with very rapid action and ready reversibility. Such features fit well with the suggestion that they act as highly specific surface active agents which are preferentially adsorbed on biological membranes.

Several theories have been put forward to account for cytoplasmic cleavage (see review by Wolpert<sup>4</sup>). Whatever the underlying mechanism, it seems likely that if a cleaving cell is attached to glass, the process cannot be properly completed unless the cell membrane is detached from the glass surface along the line of the cleavage furrow. If cytochalasins increase the adhesion between cell and glass, they could slow down or prevent this detachment. The development of a cleavage furrow might also be retarded by an increase in surface viscosity produced by adsorption of cytochalasin. The cleavage mechanism is closely involved with the presence of the mitotic apparatus. The orientation and position of this apparatus determine the subsequent position of the line of cleavage. In order to prevent cleavage, therefore, it may only be necessary to slow down the process of furrowing. The mitotic apparatus is dismantled shortly after nuclear division, and if furrowing is not completed by this time, the relevant mechanism may no longer operate, and the furrow will retreat.

The mechanism of cell motility is poorly understood and many theories have been advanced. The theory of cell movement I have previously put forward<sup>5,6</sup> is particularly

amenable to the interpretation of cytochalasin effects in terms of surface activity. According to this theory, cell movement is basically the result of cell extension by "passive" spread over a surface which can be wetted by the cell. On a heterogeneous surface, the cell moves in a direction which represents an increase in cell to substrate adhesion. This can be shown experimentally using surfaces of graded adhesiveness. Cells move up such an adhesion gradient with improved efficiency and in a highly directional manner. I have suggested the name "haptotaxis" to refer to cell movement in the direction of increased cell to substrate adhesion. Haptotaxis is proposed as the key principle in determining the motile behaviour of tissue cells. The specific application of this idea to the interpretation of contact inhibition, cancer invasion and chemotaxis has previously been discussed<sup>5</sup>. Cell motility on a homogeneous surface can also be interpreted as a result of haptotactic movement. In this case the difference in substrate adhesiveness which determines cell movement is considered to be created by the cell itself. The leading edge of a cell moving on glass is breaking new ground on a clean area of substrate. This could allow the leading edge to maintain a permanent advantage over the trailing edge where the glass surface may be rendered less adhesive through contamination by previous contact with the cell. The theory may be applied to an idealized cell of circular shape moving on a uniform flat surface. The theory then requires that the boundary tension forces tending to move the cell are proportional to its circumference, whereas the frictional forces tending to resist movement are proportional to its area. Area increases as the square of the circumference, so if cell to substrate adhesion is progressively increased, a point will be reached at which the sum of the restraining forces exceeds the forces tending to move the cell. At this point the cell can no longer move. Such a mechanism may underlie the effect of cytochalasin *B* on cell motility. It is interesting to note that "epithelial" cells in culture—usually so called because they tend to be flattened and relatively well spread on glass—are relatively immobile. Cultured cells which normally show rapid movement on glass sometimes produce polyploid giant cells. These cells tend to occupy a disproportionately large area of glass and are generally incapable of movement.

Cytochalasins also inhibit the ruffling movements at the margins of certain motile cells. I have interpreted ruffle formation as the result of a local retreat of the cell margin, causing a piling up of cell material. This retreat is considered to occur in the face of advancing culture medium which is successfully competing for contact with the glass at these points. An increase in the adhesion of the cell to glass due to the adsorption of cytochalasin at this interface would be expected to inhibit ruffle formation if this interpretation of ruffling is correct. If cytochalasins have an effect on surface viscosity as previously suggested, this could also be expected to impede cell movement and ruffle formation.

The explanation for nuclear extrusion follows a similar pattern. In this case, however, it is necessary to postulate adsorption of cytochalasin at an internal cell interface. This might account for the fact that nuclear extrusion requires a higher concentration of compound than the other effects. If cytochalasin is adsorbed on the internal surface of the cell membrane, or on the external surface of the nuclear membrane, it might lower the boundary tension between them. Increased adhesion between these structures would increase the area of any region of chance contact, and tend to make the cell membrane wrap itself closely round the nucleus until it was virtually excluded from the cell. Although it could be almost completely pinched off in this way, the nucleus would remain attached so long as the cell membrane remained intact. The essentially competitive nature of adhesion was emphasized in relation to the adhesion of cells to glass in the presence of culture medium. Similarly, adhesion between nucleus

and cell membrane cannot be fully treated without reference to cytoplasmic fluid acting as a third phase. Again it should be made clear that adhesion between nucleus and cell membrane could involve surface effects at more than one of the three interfaces concerned.

A curious and puzzling observation was made at an early stage in these investigations. Nuclear extrusion occurred more frequently in cells cultured in perfusion chambers than when they were grown in Petri dishes. The significant difference proved to be that cells in the perfusion chambers were attached to the under surface of the cover glass. It seemed unlikely that gravity could play a significant part in nuclear extrusion, as gravitational forces are exceedingly small at the cellular level. The mechanism proposed for nuclear extrusion provides a ready explanation. When cells are growing on the upper surface of a cover glass, the nucleus may fall under gravity within the cell and make contact with the lower cell membrane. In this region the cell membrane is not free to wrap round the nucleus because it is more strongly adherent to the glass substrate.

**Potential value of cytochalasins.** The cytochalasins produce a remarkable range of interesting biological effects. By interfering with specific cell activities such as cytoplasmic cleavage and cell movement, they should prove useful as research tools for investigating these important aspects of cell biology. Their potency, reversibility, and lack of general toxicity are particularly valuable features in this connexion. Their action in preventing cytoplasmic cleavage makes it possible to produce polyploid cells at will. This could be of value, for example, in determining the influence of different, known degrees of polyploidy on specific aspects of cell behaviour

and function. The possible significance of apparent mitotic synchrony in multinucleated cells without nuclear doubling has already been mentioned. The elucidation of this problem could have important consequences for the physiology of mitosis. The use of these compounds for the non-surgical removal of cell nuclei seems to offer new opportunities for investigating the functional relationship of nucleus and cytoplasm. Complete enucleation only occurs in a proportion of cells, but refinements in technique may make it possible to enucleate entire cell populations. When fully extruded, the connecting thread between nucleus and cytoplasm is extremely tenuous. This must restrict any functional interchange between them and may prevent it altogether. If so, it may not be necessary to enucleate the cell completely in order to study some aspects of the interdependence of nucleus and cytoplasm. Because nuclear extrusion is reversible, short-term experiments of this kind may have the additional advantage of allowing the restoration of the nucleus at a later stage.

Many experimental uses for these compounds can be envisaged. Whether or not their usefulness is likely to extend beyond the laboratory will only become apparent when they have been investigated more widely.

I thank Miss Elaine Bowker for technical assistance.

## Is an Ectoproct Possible?

by

CHARLOTTE P. MANGUM

THOMAS J. M. SCHOPP

Department of Biology, College of William and Mary, Williamsburg, Virginia, and The Systematics-Ecology Program, Marine Biological Laboratory, Woods Hole, Massachusetts

The deficit between predicted and observed rates of oxygen consumption in a small sedentary aquatic invertebrate suggests that there may be circulation of fluid in the body cavity

MEMBERS of the phylum Ectoprocta (Bryozoa) are usually considered to be organisms of sufficiently small volume and large surface area to preclude a selective advantage for specialized respiratory and circulatory mechanisms<sup>1</sup>. Respiratory exchange is believed to occur by means of passive diffusion of oxygen and carbon dioxide across the surface of tentacles. To test the hypothesis that passive diffusion can supply sufficient oxygen to an ectoproct, we compared measured rates of oxygen consumption with those predicted from a model based on ectoproct morphology.

A representative of the class Gymnolaemata, which includes a large majority of all ectoproct species, was chosen. Colonies of *Bugula turrita* (Desor) were collected during late June and July from shallow waters of Eel Pond, Vineyard Sound, Massachusetts, at environmental temperatures of 18°–23° C. Approximately 6,000 healthy zooids were carefully cleaned under a dissecting microscope with fine forceps and brushes, and acclimated to 20° C for 24 h before a series of measurements of oxygen uptake were made. The rate of oxygen consumed by undisturbed animals (lophophores extended) was measured under conditions of constant oxygen concentration at 20° C and

32 ‰ salinity with an adaptation of the Scholander volumetric respirometer<sup>2</sup>. The result was 3.7 ( $\pm 0.7$  S.D.) mm<sup>3</sup> of oxygen/mg dry wt. (excluding skeleton)/h, or  $4.5 \times 10^{-4}$  mm<sup>3</sup>/zoid/h. The only previous measurement of oxygen consumption by an ectoproct of which we are aware is that of Robbie<sup>3</sup>, who gives 2.1 mm<sup>3</sup>/mg of dry wt. (excluding skeleton)/h at 25° C for an unidentified ectoproct from Bermuda.

To calculate the hypothetical rate of oxygen consumption in *B. turrita* that could be maintained by diffusion alone, we considered a model consisting of fourteen small cylinders (lophophore tentacles) mounted on a larger cylinder (tentacle sheath), in turn supported by a rectangular prism (zoecium). External and internal dimensions of the model are given in Figs. 1 and 2. Tentacles and tentacle sheath consist of a single layer of cells surrounding a coelomic space. The zoecium is completely covered by a chitinous layer which is reinforced by calcium carbonate on all but the ventral (frontal) surface. The dry weight of each of the three zoid subdivisions was calculated by assuming that weight is directly proportional to volume (Table 1).

If no circulation of the coelomic fluid occurs, then we

Table 1. SUMMARY OF OXYGEN CONSUMPTION IN A SINGLE INDIVIDUAL OF *Bugula turrita* IN OBSERVED AND HYPOTHETICAL SYSTEMS

Part of animal	Percentage volume	Dry weight (excluding skeleton) (mg $\times 10^{-5}$ )	Hypothetical rate of oxygen consumption (mm <sup>3</sup> /h)		Observed rate of oxygen consumption (mm <sup>3</sup> of oxygen/h $\times 10^{-4}$ )
			Diffusion without circulation $\times 10^{-3}$	Diffusion with circulation $\times 10^{-3}$	
Lophophore	6.1	7.0	23.9	2.1	2.6
Tentacle sheath	6.8	7.8	0.3	0.15	2.9
Zoecium	87.1	100.2	0.04	—	37.0
Whole animal	100.0	115.0	24.2	2.25	42.5

Values for each subdivision of the whole animal are based on an assumption of uniform rate of oxygen consumption in each part.

can use the equation developed by Gerard<sup>4</sup> to estimate the amount of oxygen which can diffuse into each of the fourteen cylinders (tentacles)

$$C_0 = \frac{Ar^2}{4D} \quad (1)$$

where  $C_0$  is the concentration of oxygen at the external surface, measured in atm.,  $A$  is the rate of consumption of oxygen, measured in mm<sup>3</sup>/mg of dry wt./min,  $r$  is the radius of the cylinder, measured in cm, and  $D$  is the diffusion coefficient of oxygen, measured in atm./cm/cm<sup>2</sup>, in tissue. The oxygen saturation value<sup>5</sup> for seawater at 20° C and 32 ‰ salinity (0.29 atm.) was used because *B. turrita* lives in well aerated habitats and because the

Fig. 1. Ventral (frontal) view of model of *Bugula turrita*. The dark region of the zoecium is covered by chitin and calcium carbonate; cross-hatched region of zoecium is covered by chitin. Dimensions in cm.

Fig. 2. Internal dimensions of a model of *Bugula turrita* (longitudinal sections). Dimensions in cm. (A) Tentacle. (B) Tentacle sheath. (C) Zoecium.

cilia of tentacles continuously renew the external medium in contact with the surface of the tentacles. The diffusion coefficient<sup>6</sup> ( $D = 2.4 \times 10^{-5}$ ) is the midpoint between the value for oxygen in coelomic fluid (seawater) and that for oxygen in epidermis (muscle and connective tissue). The ratio of coelomic fluid to epidermis in tentacles is 1:1 (Fig. 1).

When the equation is solved for  $A$  the tentacle is shown to be able to support a rate of oxygen consumption in its own tissue of  $3.4 \times 10^2$  mm<sup>3</sup>/mg/h, or the lophophore to support a rate of  $2.4 \times 10^{-1}$  mm<sup>3</sup>/h. The rate observed for the lophophore is  $2.6 \times 10^{-4}$  mm<sup>3</sup>/h, assuming a uniform rate of oxygen consumption in all parts of the animal. The excess of oxygen diffusing into tentacles could, therefore, be approximately a thousand times that consumed by them. If the loss of oxygen in diffusion is limited to that taken up by the epidermis, then the concentration of oxygen in the coelomic fluid of tentacles could be 99.9 per cent of that in the external medium.

The same equation was applied to the tentacle sheath using appropriate dimensions for  $r$  (Fig. 2) and a diffusion coefficient<sup>6</sup> ( $D = 2.3 \times 10^{-5}$ ) calculated from the observed 52 per cent gut and 48 per cent coelomic fluid. The rate of oxygen consumption made possible by diffusion from the external medium is 37.9 mm<sup>3</sup>/mg/h, or  $29.6 \times 10^{-4}$  mm<sup>3</sup>/h for the tentacle sheath. This is approximately ten times larger than the amount consumed by the tentacle sheath (Table 1). The concentration of oxygen in the

coelomic fluid of the tentacle sheath could be 90.2 per cent of that in the external medium.

If the calcium carbonate layer of the skeleton is impermeable, then diffusion from the external medium into the zoecium can occur only through the ventral (frontal) surface which consists of chitin alone (Fig. 1). For the calculation of diffusion into the zoecium, the equation was modified to the form

$$C_0 = \frac{Ad}{D} \quad (2)$$

where  $d$  is depth of zoecium, measured in cm. The diffusion coefficient<sup>6</sup> ( $D = 2.7 \times 10^{-5}$ ) was calculated from observed 70 per cent coelomic fluid, 25 per cent gut and epidermis, and 5 per cent chitin. Solution of the equation gives a possible rate of oxygen consumption of only  $2.9 \times 10^{-2}$  mm<sup>3</sup>/mg/h, or  $2.9 \times 10^{-5}$  mm<sup>3</sup>/h for the zoecium. The observed rate is more than a hundred times larger than the hypothetical value (Table 1).

The amount of oxygen reaching the zoecium could be supplemented, of course, by diffusion within the organism. To calculate the rate of consumption of oxygen that could be supported by diffusion from the tentacles, and from the sheath into the zoecium, the diffusion equation was modified to

$$C_{01} - C_{02} = \frac{Ad}{D} \quad (3)$$

where  $C_{01} - C_{02}$  is oxygen concentration gradient, measured in atm., and  $d$  is distance over which diffusion occurs, measured in cm. For diffusion of oxygen from the coelom of the tentacle to the coelom of the tentacle sheath, the gradient of oxygen concentration is  $0.289 - 0.260 = 0.029$  atm., and the distance,  $d$ , is the height of the tentacle sheath (Fig. 1). When the equation is solved for  $A$  the result is  $6.6 \times 10^{-3}$  mm<sup>3</sup>/mg/h, or  $5.2 \times 10^{-7}$  mm<sup>3</sup>/h for the tentacle sheath. For diffusion of oxygen from the coelom of the tentacle sheath into the coelom of the zoecium, the oxygen concentration gradient is  $0.260 - 0.000 = 0.260$  atm., and the distance,  $d$ , is the length of the zoecium (Fig. 1). Solution of the equation gives  $8.8 \times 10^{-3}$  mm<sup>3</sup>/mg/h, or  $8.8 \times 10^{-6}$  mm<sup>3</sup>/h for the zoecium. Thus, the rate of oxygen consumption that is possible by means of diffusion from the external medium, plus the rate possible by diffusion from other parts of the organism, is approximately three hundred times less than the observed rate for 87.1 per cent of the animal, that is the zoecium (Table 1).

Diffusion of oxygen within the organism could be facilitated by juxtaposition of two physiologically distinct forms of a respiratory pigment in an oxygen transfer system, even if efficient circulation does not occur. The existence of a substance that could transfer oxygen was postulated by Schneider<sup>7</sup>, who found large amounts of iron in ectopros, and his finding has recently been confirmed (unpublished results of Schopf and Manheim). The concentration of ferrous oxide in *B. turrita* is 0.57 per cent of the dry weight (excluding the skeleton), compared with 0.01 per cent to 0.1 per cent in an organ such as the mammalian liver, which is rich in iron<sup>8</sup>.

We attempted to detect an iron metallo-porphyrin by forming a pyridine haemochromagen from crude extracts of *B. turrita*, obtained from 1,288 mg (wet weight) which were homogenized in 4 ml. of seawater. The extract was centrifuged and the supernatant was filtered. The procedure was repeated, using distilled water as the solvent. After addition of 1 ml. of pyridine and sodium thio-sulphate, we were unable to detect the absorption peaks, with a Beckman DU spectrophotometer, of a pyridine haemochromagen in either extract. We have not excluded the possibilities of haemerythrin or an unknown oxygen transfer substance, but we can conclude that significant

quantities of haemoglobin are absent. It seems more likely that iron in *B. turrita* is bound with skeletal components.

Robbie<sup>9</sup> has demonstrated the sensitivity of ectopros to hydrogen cyanide, and so respiration cannot be primarily anaerobic. The remaining alternative is that, contrary to current belief, circulation of the coelomic fluid does occur. This suggestion was tested by calculating the hypothetical rate of oxygen consumption which could be maintained by diffusion combined with effective circulation. A modification of the equation for respiration with circulation, given by Krogh<sup>6</sup> to a form suitable for a cylinder, is

$$C_0 = \frac{ArT}{2D} \quad (4)$$

where  $T$  is thickness of epidermis, measured in cm. Solution of the equation for  $A$  shows that the fourteen tentacles of the lophophore can support a rate of oxygen consumption of  $2.1 \times 10^{-1}$  mm<sup>3</sup>/h, which is two hundred times greater than the observed rate of  $4.3 \times 10^{-3}$  mm<sup>3</sup>/h for the whole animal. Similarly, diffusion through the tentacle sheath, followed by circulation, could supply significant amounts of oxygen to the animal (Table 1). The large excess of oxygen provided by the tentacles and the tentacle sheath easily accounts for the oxygen consumption by the whole animal.

The hypothesis of efficient circulation can explain the observed rate of oxygen consumption, but does it occur? A systematic pattern of circulation of coelomic fluid has been demonstrated in only one gymnolaemate ectoproct, the freshwater species *Paludicella articulata*, in which localized tufts of cilia which line the coelom cause fluid movement<sup>10</sup>. Careful microscopic observation of living individuals provided no evidence of a similar mechanism in *B. turrita*.

A well known rhythmic behaviour pattern of ectopros may be important in effecting the circulation of the coelomic fluid<sup>11</sup>. Periodically, an undisturbed zoid undergoes a sudden, rapid retraction from the extended feeding position to a withdrawn position within the zoecium, which is immediately followed by expansion to the extended state. Distortion of the coelom accompanying the cycle must cause movement of the coelomic fluid. Observation of ten retraction-expansion cycles in each of ten zoids in natural seawater at 23° C indicates that the period of the cycle is 39 ( $\pm 49$  S.D.) sec. This mechanism of circulation would not be completely efficient, but its frequency seems sufficient to explain the observed rate of oxygen consumption.

We conclude that oxygen consumption of the gymnolaemate ectoproct *Bugula turrita* cannot be explained by the diffusion of oxygen from the external medium unless circulation of the internal medium occurs. Coelomic cilia could not be demonstrated, and so we suggest that the rhythmic expansion and withdrawal of the animal causes circulation of the coelomic fluid.

# Piezoelectricity as a Fundamental Property of Biological Tissues

by

MORRIS H. SHAMOS

Department of Physics,  
New York University, New York

LEROY S. LAVINE

Department of Orthopedic Surgery,  
State University of New York,  
Downstate Medical Center,  
New York

Piezoelectric effects have been produced in a number of soft tissues, as well as hard, and appear to be associated with the presence of oriented fibrous proteins such as collagen. Thus, piezoelectricity may be a universal property of living tissue, and may play a significant part in several physiological phenomena

In a little less than two decades, evidence has accumulated that points to a previously unrecognized property of biological tissues—an electromechanical phenomenon that closely resembles the well known classical piezoelectric effect in crystalline solids. Although this effect has so far been observed in relatively few different kinds of tissue, chiefly in connective tissue, it seems highly probable that piezoelectricity is a property of most, if not all, tissues in the plant and animal kingdoms. If this is so, it may be possible to account for a number of biological phenomena that appear to be mechanically induced. It may ultimately be possible to trace many phenomena such as bone remodelling, the formation of thrombi due to injury of blood vessels, and the entire range of tactual responses, including the sense of hearing, to this basic biophysical property of tissue.

Piezoelectricity has so far been demonstrated in wood<sup>1,2</sup>, in ramie and silk fibres<sup>3</sup>, in bone<sup>4-6</sup> and in tendon<sup>7,8</sup>. In all these cases the usual criteria for classical piezoelectricity were shown to apply: for example, linearity and reversibility (direct and converse effects). Moreover, the form of piezoelectric tensor was determined or verified in each case. One group of investigators, who made some qualitative observations of electric polarization in bone under bending stress<sup>9,10</sup>, holds that the classical piezoelectric effect is inadequate to account fully for the observed phenomenon. The weight of the evidence, however, strongly supports the classical view.

For completeness it should be noted that perhaps the first indication of a piezoelectric effect in biological tissue was reported in 1941 by Martin<sup>11</sup>, who observed an electric polarization in bundles of wool and hair when subjected to stress. He also observed a pyroelectric effect in these materials under large thermal gradients.

It seems clear that the piezoelectric effect, even in hard tissues, can be attributed to the main organic constituent of the tissue: that is, collagen in the case of bone and tendon, and cellulose in wood. The effect is highly directional, with a maximum for shear stresses and a minimum for pure compressive or tensile stresses. In long bone, for example, where the direction of collagen fibres may or may not be parallel to the axis of the bone, the maximum is found for stresses directed at 45° to the collagen axis. The same is true of the fibrous molecules in wood and tendon.

The piezoelectricity apparently stems from a shearing stress on oriented long chain fibrous molecules, the actual effect being a displacement of charge due to the distortion

of cross-linkages in the molecular structure, probably hydrogen bonds. Thus a requirement for piezoelectricity in living tissue is the presence of a well ordered asymmetric fibrous molecule, cross-linked to form a uniaxial system which can be polarized by a shearing stress.

All connective tissue contains one or more kinds of fibrous molecule such as collagen, keratin, elastin, reticulum, or cellulose, and in general these molecules have a sort of "crystalline" structure in the sense of a short range asymmetry, if not an overall morphological order. It therefore follows, if our understanding of the origin of this effect is correct, that soft tissues should also be expected to have piezoelectric properties.

To test this hypothesis we have investigated the electromechanical effects in several soft tissues. Specimens of skin, callus (stratum corneum) and cartilage were dried, electrodes affixed, and the direct piezoelectric coefficient observed by a simple method which also allows us to determine the form of piezoelectric tensor in each case.

Specimens are normally cut in the form of thin disks, about 1.3 cm in diameter and 0.1–0.2 cm thick, arranged so that the axis of the fibre in each case is essentially in the plane of the disk. They are dried by desiccation for at least 24 h after removal from the host, following which a conductive epoxy is applied to the faces and allowed to harden with thin connecting wires in place. Some of the soft tissues investigated, such as human skin, were an order of magnitude thinner but were otherwise prepared in the same manner.

In the dry state these materials have volume resistivities in the order of  $10^{12}$  ohm cm at room temperature, which places them in the category of fairly good insulators exhibiting intrinsic conductivity with an energy gap of about 1.0–1.5 eV. We have been unable to find evidence of rectification or photoelectric effects in bone, as has been reported by others<sup>10,12</sup>. In fact, a careful search for these effects has revealed a simple experimental artefact that appears to be the explanation for the reported photoconductivity<sup>13</sup>.

Observation of the direct piezoelectric effect is carried out in the following way: a dynamic technique is used to eliminate possible spurious direct current potentials. An electromagnetic force generator, driven at a fixed frequency (generally 50 c/s) by a signal generator, exerts an alternating stress on a clamped specimen. The resulting polarization of the specimen is observed as a surface charge on the electrodes. A high input impedance ampli-

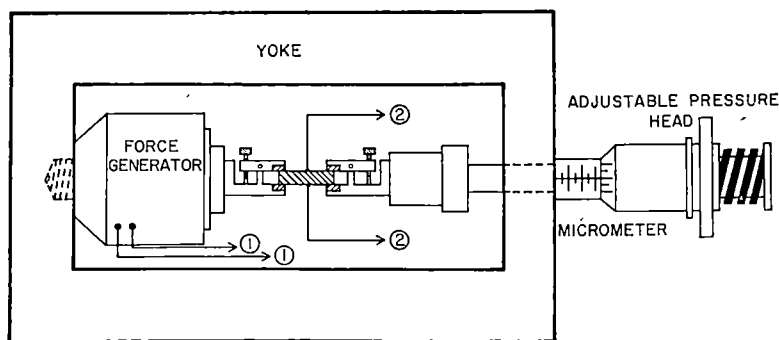

Fig. 1. Yoke assembly for direct piezoelectric measurements showing force generator and clamped specimen (hatched). 1, Input to force generator; 2, output to amplifiers.

Fig. 2. Relative piezoelectric coefficient ( $d'_{13}$ ) as function of angle for three specimens of human femur. Zero direction is taken along bone axis. Direct effect: input 0.5 amp, 100 c/s, measured at 28° C, RH < 20 per cent.

fier is used for this purpose, followed in those cases where the piezoelectric coefficient may be very small by a tuned amplifier adjusted to the driving frequency\*. The final output is recorded by an alternating current voltmeter and the phase is observed on an oscilloscope or with a simple phase meter†.

A diagram of the yoke assembly used to clamp the specimen and maintain a rigid alignment of force generator and specimen is shown in Fig. 1. (The specimen is shown in edge view.) The micrometer head provides an adjustable stress to the specimen, which is particularly important when soft tissues are used. The entire yoke assembly is suspended in an oven for temperature control and electrostatic shielding. All measurements reported here were made at room temperature (24°–28° C) and about 20 per cent relative humidity.

To determine the angular dependence and ultimately the form of piezoelectric tensor for a given material the sample is rotated stepwise through 180° measured from some arbitrary reference axis. Examples of typical data obtained from hard tissues are shown in Figs. 2 and 3. Fig. 2 shows the variation of piezoelectric coefficient ( $d'_{13}$ ) with angle for three specimens cut from the same human femur. The specimens were disk-shaped and were cut from the same plane just below the neck of the femur; their location in the femur is shown in top view in the figure. The plane of each disk is parallel to the bone axis, which is taken as the zero direction for determining the angular dependence. Each curve shows the sin 2θ

\* This is normally not required in the case of bone, where the maximum piezoelectric effect is about one-tenth that of quartz. When observing the angular dependence, however, the additional gain is useful in determining the points at which the polarity reverses.

† Observing the phase angle between the output voltage and the driving voltage for the force generator permits determination of the sign of the piezoelectric coefficients.

behaviour to be expected of a uniaxial piezoelectric material in which the predominant piezoelectric stress is a shear. Two are, however, displaced from the origin by amounts that reflect the fact that the collagen axis of symmetry in human femur is displaced about 10° from the bone axis; that is, the principal collagen axis, at least as shown by X-ray diffraction patterns<sup>4</sup>, is vertical in the standing position while the femur axis is not. The sensitivity of the technique is readily apparent from this

Fig. 3. Relative piezoelectric coefficient ( $d'_{13}$ ) as function of angle for two specimens of human mandible. ●, Sample 1; ○, sample 2. Direct effect: input 0.5 amp, 50 c/s, measured at 24° C, RH 20 per cent.

set of curves. By way of contrast, no such displacement is found in the humerus.

Fig. 3 shows similar curves from two samples cut from the same human mandible. The shift in these curves is also attributed to the change in orientation of collagen fibres relative to the bone direction at the two sites from which the samples were taken. It is important to note,

incidentally, that we find little or no piezoelectricity in tooth enamel, whereas dentine exhibits a marked effect. This accords with the view that the piezoelectric effect in hard tissues originates in the fibrous molecular constituent rather than the mineral phase.

Fig. 4 shows the results obtained with soft tissues. Here, the same general pattern is observed, indicating a fibrous molecular (protein) structure with a marked uniaxial asymmetry. In one of these (human skin) the shape of the curve suggests a dual orientation, as though the main fibrous structure (collagen and elastin) in adjacent layers of the corium is alternately shifted through 90°. There is some histological evidence to support this picture of collagen orientation in skin<sup>14</sup>. The lack of symmetry between positive and negative portions of the other curves, particularly the callus specimen, is probably attributable to non-uniform thickness of the samples.

Although these observations show only that dried tissues exhibit marked piezoelectric properties, and it remains to extend such investigations to the more physiological state, the apparent universality of the effect suggests that it may play a very basic part in physiology, particularly in regard to homeostasis. A new link may thus be provided between biology and physics.

This work was supported by grants from the U.S. National Institutes of Health and the U.S. Atomic Energy Commission.

We thank Mrs. L. Perl for valuable assistance in performing the measurements, and Dr. E. Fukada for helpful suggestions.

## Amino-acid Replacements in Horse Haemoglobin

by  
J. V. KILMARTIN  
J. B. CLEGG\*

Medical Research Council Laboratory of  
Molecular Biology, Cambridge, England

Horse haemoglobin contains up to four components which arise by substitution of glutamine for lysine at position  $\alpha 60$  and of tyrosine for phenylalanine at position  $\alpha 24$ . The possible genetic reasons for this heterogeneity are discussed

HORSE haemoglobin consists of two electrophoretically distinct components<sup>1,2</sup>. Previous investigations have failed to reveal the nature of the difference between them<sup>3,4</sup>, but after the recent elucidation of the sequence of amino-acids in the electrophoretically slow component<sup>5,6</sup> it seemed worth while to re-investigate the problem. We find the difference to be a result of the replacement of the lysine at position 60 in the  $\alpha$ -chain of the slow component by glutamine in the fast component.

In addition, of the haemoglobins of twenty-three individual horses investigated, nine had both tyrosine and phenylalanine in position 24 of the fast and slow

$\alpha$ -chains, which gave a total of four haemoglobins; three had tyrosine only and eleven had phenylalanine only in this position.

Horse haemoglobin was converted to globin by the 2 per cent acid acetone method without previous fractionation of the fast and slow components. Separation of the  $\alpha$ -chains and  $\beta$ -chains and conversion of the separated chains to the aminoethylated derivatives was carried out as described by Clegg *et al.*<sup>7</sup>. The resulting fractionation is shown in Fig. 1. Tryptic digestion of the aminoethylated derivatives was carried out for 3 h at 37° C in 1 per cent ammonium carbonate, pH 9, at a protein concentration of 1 per cent and a trypsin to protein ratio of 1:100. The

\* Present address: Department of Medicine, University of Liverpool.

digestion mixture was freeze-dried three times—on the two last occasions from water made alkaline by blowing ammonia vapour over its surface.

Fingerprints of the three fractions were prepared by subjecting portions of the digests to electrophoresis at pH 6.5, followed by descending chromatography in BAWP (butanol : acetic acid : water : pyridine (15 : 3 : 12 : 10 by volume)). They were then dipped in 0.25 per cent ninhydrin in acetone and developed at 60° C. Tracings of the resultant patterns are shown in Fig. 2. Additional fingerprints of the three peaks were also stained for histidine, arginine, tyrosine, sulphur and tryptophan<sup>4</sup>.

From a knowledge of the amino-acid sequence of the slow fraction of horse haemoglobin and a comparison with fingerprints of human  $\alpha$ -chains and  $\beta$ -chains, all the chief spots in the three fingerprints were identified (Fig. 2). These identifications were confirmed by the fingerprints stained for specific amino-acids and by amino-acid analysis of the peptides eluted from fingerprints stained with 0.025 per cent ninhydrin in acetone<sup>7</sup>.

The first peak eluted from CM cellulose was shown to be  $\beta$ -chain and the second and third peaks were  $\alpha$ -chain. Thus, the first (that is, the more acidic)  $\alpha$ -chain ( $\alpha_f$ ) to be eluted must have been derived from the electrophoretically fast (that is, the more acidic) haemoglobin component and the second, more basic,  $\alpha$ -chain ( $\alpha_s$ ) from the slow component.

The fingerprint of the  $\alpha_f$  chain is characterized by the presence of a new peptide  $\alpha_f$  7,8 and the absence of peptides  $\alpha_s$  7,  $\alpha_s$  7,8, and  $\alpha_s$  8,9 normally found in fingerprints of the  $\alpha_s$  chain. The compositions of these peptides are shown in Table 1; clearly the data can be explained by the substitution of a glutamic acid (or glutamine) for a lysine at position 60 in the  $\alpha_s$  chain as shown in Fig. 3.

Table 1. COMPOSITION OF PEPTIDES OF THE  $\alpha$  CHAINS

	$\alpha_f$ 7,8	$\alpha_s$ 7	$\alpha_s$ 7,8	$\alpha_s$ 8	$\alpha_s$ 8,9
Lysine	1.1	1.0	1.0	1.0	2.0
Histidine	1.0	1.1	1.0		2.9
Aspartic acid					5.0
Threonine					1.1
Serine					1.9
Glutamic acid	1.0				
Proline					1.0
Glycine	1.0	1.0	1.1		3.0
Alanine	0.9	0.9	1.0		4.2
Valine					2.0
Leucine					6.9

Thus, in the absence of a lysine-lysine bond at position 60–61 in the  $\alpha_f$  chain, the formation of peptides comparable with  $\alpha_s$  7,  $\alpha_s$  7,8, and  $\alpha_s$  8,9 is prevented, with the result that only one peptide ( $\alpha_f$  7,8) is produced from this region of the  $\alpha_f$  chain on digestion with trypsin, instead of the three (and free lysine) normally found in digests of the  $\alpha_s$  chain.

We deduced the substituent to be glutamine rather than glutamic acid, for digestion of  $\alpha_f$  7,8 with "pronase"

Fig. 1. Separation of the chains from 80 mg of horse globin on a 1 × 10 cm CM cellulose column. The chains were eluted at 1 ml./min by applying a linear Na<sup>+</sup> gradient made by mixing 150 ml. of 0.005 molar Na<sub>2</sub>HPO<sub>4</sub> and 150 ml. of 0.03 molar Na<sub>2</sub>HPO<sub>4</sub>, both adjusted to pH 6.5 with phosphoric acid and made 8 molar in urea and 0.05 molar in 2-mercaptoethanol. Peak X appeared in variable amounts and gave a fingerprint which appeared identical with that of the  $\beta$ -chain.

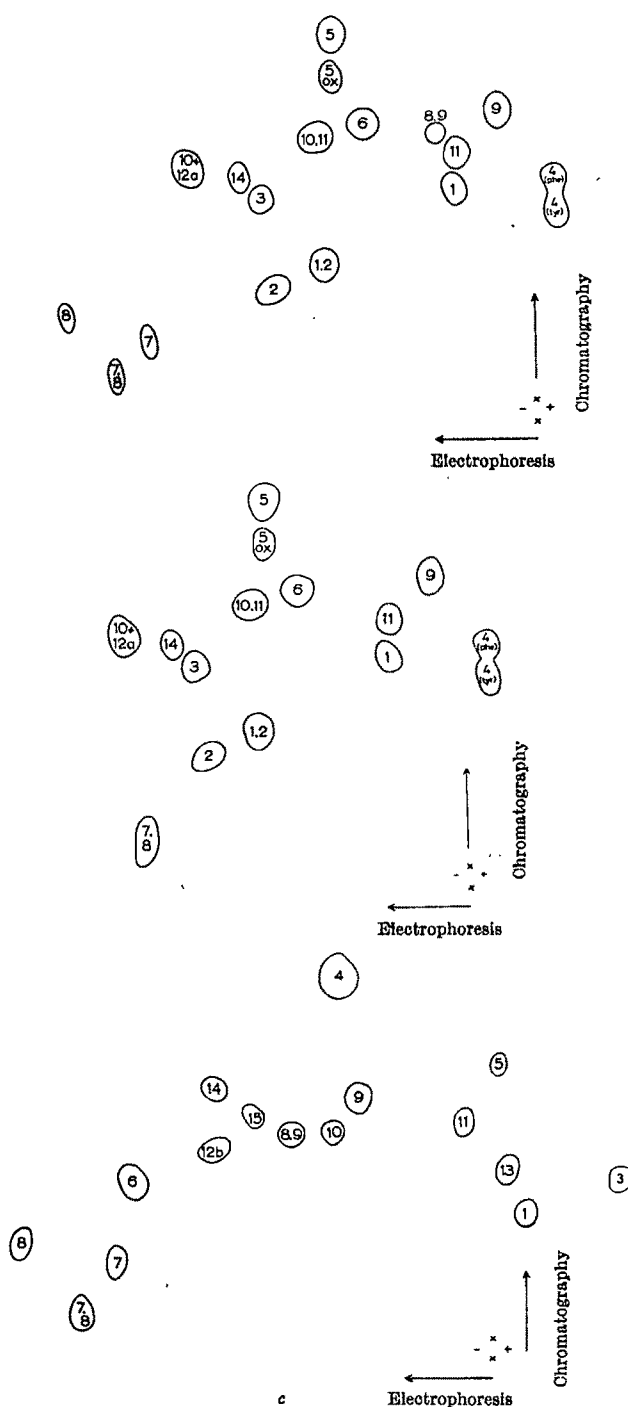

Fig. 2. Tracings of fingerprints of (a) amino ethylated  $\alpha_s$  chain, (b) amino ethylated  $\alpha_f$  chain, and (c) amino ethylated  $\beta$ -chain. We were unable to find  $\beta$ 2 or  $\beta$ 12a in fingerprints of amino ethylated  $\beta$ -chain although the peptides both before and after these in the  $\beta$ -chain were found in good yield. Peptides are numbered sequentially starting from the N-terminal end of the protein chain.

gave a peptide of composition histidine, glycine, glutamic acid (after acid hydrolysis), basic at pH 6.5, and another of composition glycine, glutamic acid neutral at pH 6.5, thus ruling out the presence of an acidic residue.

Our results are consistent with those of Perutz *et al.*<sup>3</sup> and Stockell *et al.*<sup>4</sup>. In fingerprints of whole fast globin the absence of peptides  $\alpha_s$  7,  $\alpha_s$  7,8, and  $\alpha_s$  8 would not have been noticed, for they are identical with the corresponding peptides of the  $\beta$ -chain and thus run in the same place. The only extra peptides seen would be  $\alpha_f$  7,8 in the fast globin and  $\alpha_s$  8,9 in the slow, which probably correspond to peptides 1 and 2 respectively in Stockell *et al.*<sup>4</sup>.

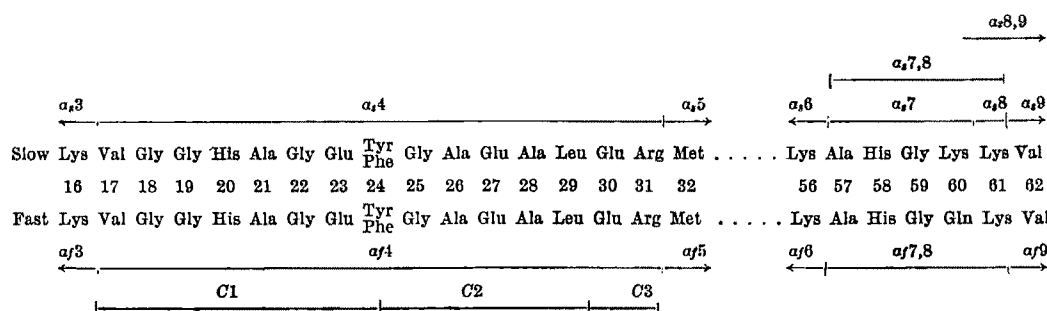

Fig. 3. Amino-acid sequences of portions of the  $\alpha$  and  $\alpha_f$  chains showing the region in which they differ.

During the analysis of the peptides eluted from the fingerprints of the  $\alpha$ -chain, peptide  $\alpha_4$  consistently gave non-integral values for both tyrosine and phenylalanine, in contrast to the reported value of one residue of tyrosine. Analysis of  $\alpha_4$  from the fast and slow  $\alpha$ -chains of several horses with both tyrosine and phenylalanine in this peptide gave 0.4 moles of tyrosine and 0.6 moles of phenylalanine/mole of peptide; these values were the same for both fast and slow chains. The peptide was partially resolved into two components by chromatography in the normal peptide mapping system and completely resolved on a long chromatographic run. The two peptides thus obtained had the normal  $\alpha_4$  composition except that the chromatographically fast component had one residue of phenylalanine and no tyrosine, and the other component had one residue of tyrosine and no phenylalanine. To confirm that the tyrosine and phenylalanine residues occurred in the same position, the mixed peptides were digested with chymotrypsin to give three peptides which separated at pH 3.5 with compositions corresponding to C1, C2 and C3 in Fig. 3. The Pauli-positive peptide C1 was chromatographed in BAWP to give two components, one which contained one residue of tyrosine and the other one residue of phenylalanine/mole of peptide. Digestion of these two peptides with carboxypeptidase A released one residue of tyrosine and one residue of phenylalanine respectively and no other amino-acids. This showed that both the  $\alpha_f$  and  $\alpha_s$  chains give two  $\alpha_4$  peptides on digestion with trypsin, one with tyrosine at position 24 and the other with phenylalanine in the same position.

Other horses were found later in which both the  $\alpha_f$  and  $\alpha_s$  chains had only tyrosine or phenylalanine at position 24. The presence of very low proportions of the second amino-acid cannot be ruled out because some tyrosine is destroyed on acid hydrolysis, and because both residues give rather broad peaks on the amino-acid analyser, making it more difficult to detect very small amounts. Also, the yield of peptides eluted off paper is low (about 20–30 per cent in the case of  $\alpha_4$ ).

The compositions of the remaining homologous tryptic peptides of the  $\alpha_f$  and  $\alpha_s$  chains appear to be identical, although double substitutions of the type  $A \rightarrow B$  and  $B \rightarrow A$  in the same tryptic peptide would not have been detected. The core (residues 105–139) has not been analysed. We have failed to find any other examples of amino-acids which occur in the  $\alpha_f$  and  $\alpha_s$  chains in non-integral amounts comparable to those at position 24.

We conclude, therefore, that there are a total of four horse  $\alpha$ -chains.

While in other mammals multiple electrophoretically distinct haemoglobins have been accounted for by differences in the non- $\alpha$ -chains<sup>8</sup>, in horse the  $\beta$ -chains appear to be identical while multiple  $\alpha$ -chains exist. Both the amino-acid replacements can be explained by the substitution of single nucleotide bases in the corresponding codons of the messenger RNA.

One obvious explanation for the tyrosine/phenylalanine heterogeneity is to assume the existence of two allelic

genes; however, because our experiments would probably not have detected very small amounts of tyrosine in horses thought to contain only phenylalanine at position  $\alpha_{20}$  and vice versa, the evidence in favour of allelic genes is not yet conclusive.

The lysine/glutamine heterogeneity has been thought to be caused by two closely linked non-allelic genes, for no animals homozygous for either lysine or glutamine (that is, slow or fast haemoglobins) have been detected<sup>2</sup>. The simultaneous presence of tyrosine and phenylalanine at position 24 of both the fast and slow  $\alpha$ -chains in some horses makes it difficult to accept this explanation, since it would imply that independent mutations had occurred at the same point in both genes.

An alternative explanation of the lysine/glutamine heterogeneity would be an ambiguity in the translation of a messenger RNA codon as postulated by von Ehrenstein<sup>9</sup> to account for multiple  $\alpha$ -chains in rabbit haemoglobin and by Rifkin *et al.*<sup>10</sup> to account for the inheritance of two mouse haemoglobins in a strain inbred for many generations.

In this context, it is noteworthy that the related donkey has only a single haemoglobin (which can be distinguished electrophoretically in two steps from the two horse haemoglobins because of the substitution of an asparagine residue for the histidine at  $\alpha_{20}$ , shown by unpublished results of Kilmartin and Clegg). The  $\alpha$ -chain of this haemoglobin seems to have only phenylalanine at position 24 and lysine at position 60. Thus, the  $\alpha$ -chain of donkey haemoglobin appears to be under the control of a single structural gene, and it would seem not unreasonable to assume that this is also the case in the horse. A distinction between these alternative interpretations of our results might be possible if a horse with a charged  $\alpha$ -chain variant could be found. If the glutamine/lysine heterogeneity were caused by two non-allelic genes, only one of the two components, either the fast or the slow, should be affected by the mutation. If it is caused by an ambiguity in the reading of the code, both components should be affected.

We thank Dr. R. K. Archer, Equine Research Station, Newmarket, and Dr. L. G. Goodwin, Nuffield Institute of Comparative Medicine, Regent's Park, London, for help. One of us (J. V. K.) thanks the Medical Research Council for a scholarship. We also thank Dr. M. F. Perutz for his interest and encouragement.

## PLANETARY SCIENCE

### Measurements of the 1.9 cm Thermal Radio Emission from Mercury

MEASUREMENTS of the thermal radio emission from Mercury at 11.3 cm have shown that the brightness temperature is approximately 300° K and does not vary significantly with phase angle<sup>1</sup>. This is not inconsistent with the observed rotation rate of Mercury of  $58.4 \pm 0.4$  days<sup>2</sup> if the thermal inertia of the planet is sufficiently great for the temperature to remain reasonably constant at the depth at which the 11 cm emission originates. It might be expected, however, that a phase effect may exist at shorter wavelengths where the radio emission originates closer to the surface and where the temperature may be more closely related to the instantaneous value of the solar radiation. It is somewhat surprising therefore that Epstein<sup>3</sup>, who observed at 3.4 mm wavelength, claims no phase effect, with an anomalously low temperature of only  $\sim 200^\circ$  K.

We have observed the thermal radio emission from Mercury at a wavelength of 1.9 cm with the 140 ft. radio telescope at the National Radio Astronomy Observatory using a tunnel diode radiometer which had a system noise temperature of 1,200° K and a bandwidth of 2 Ge/s. The root mean square noise fluctuations were equivalent to a source of 0.15 flux units\* ( $0.02^\circ$  K) with an output time constant of 10 sec. The flux density of Mercury varied from about 1.5 flux units near superior conjunction to about 4.4 flux units near inferior conjunction. In order to minimize the effect of atmospheric noise fluctuations, the receiver was switched between the main beam (directed along the electrical axis of the paraboloid) and an offset reference beam pointed 6.5 (about 3 half power beamwidths away).

The observations were made in February and March 1966, and during this time Mercury moved from superior conjunction to just past inferior conjunction. The procedure used was to scan the antenna in hour angle at a rate of 2' arc/min such that the planet moved through a half-power beamwidth in 1 min. The measurements were confined to within  $\pm 1$  h of hour angle to minimize the effect of the decrease in antenna gain with increasing zenith angle. Observations of the source 3C 273 at a nearby declination over a range of hour angles showed that the relative gain was given by

$$G(h)/G(0) = (1 - ah^2)$$

where  $a \approx \frac{1}{2} \times 10^{-4}$  and where the hour angle  $h$  is expressed in minutes of arc.

The direction in which the telescope pointed was known to be sufficiently accurate so that over a period of a few hours near transit positions several minutes of arc apart could be set with a relative accuracy of a few seconds of arc. Because the absolute pointing varied by as much as 30" from day to day, however, we adopted the following procedure. Successive scans in right ascension were made at several declinations over a range of about 2' arc near the expected position of the planet. Examples of several such scans are shown in Fig. 1. At each declination the amplitude of the scan in right ascension was determined and the corresponding value at the meridian was found by correcting for the change in gain of the telescope

with hour angle. These amplitudes were then plotted as a function of relative declination which was corrected for the slight motion of the planet in declination during the course of the observations. The antenna temperature of the planet was determined from the best fitting curve through the measured points. Each day's measurements were referred to a noise tube calibration. The consistency of the noise tube was established from measurements of a number of non-thermal sources which were observed throughout the period. The measured antenna temperatures were converted to flux densities by means of observations of a number of standard sources. We have assumed flux densities of 28, 4.6 and 2.4 flux units respectively for Virgo A, Hydra A, and 3C 161 and disk temperatures of 500° K, 180° K and 200° K for Venus, Jupiter and Saturn respectively. During the course of these observations Mercury moved from declination  $-6^\circ$  to  $+5^\circ$ , in which range the relative gain of the antenna changed by 25 per cent. The uncertainty in this change is probably not more than 5 per cent and we estimate that the overall calibration is not in error by more than 15 per cent.

The equivalent temperature of a black-body disk is plotted in Fig. 2 as a function of planetocentric phase angle,  $\theta$ . A clear phase effect is apparent with a minimum temperature which occurs somewhat before inferior conjunction. The best fitting phase law of the form

$$T_{BB} = T_0 + \Delta T \cos(\theta + \phi)$$

gives  $T_0 = 288^\circ \pm 7^\circ$  K,  $\Delta T = 75^\circ \pm 13^\circ$  K and  $\phi = 38^\circ \pm 17^\circ$ . The quoted errors do not include the uncertainty in the calibration of the flux scale. The mean value of 288° K is in good agreement with the value found at 11 cm and is close to the value expected from solar heating. The positive sign of the phase angle  $\phi$  is consistent with a forward direction of rotation as the minimum temperature occurs before inferior conjunction when the sub-earth point is in the region after midnight on Mercury.

More recent observations at 3.4 mm (Epstein, private communication) give a phase curve the mean temperature, temperature variation and phase lead of which are in substantial agreement with the values we have found at 1.9 cm. This is contrary to the earlier report that there was no significant variation of temperature with phase angle at 3.4 mm (ref. 3). Evidence for a pronounced phase dependence at an intermediate wavelength of 8 mm has also been reported by a group of Soviet observers.

Because of its highly eccentric orbit, the temperature of Mercury at any particular phase angle probably varies

Fig. 1. Scans through the planet Mercury made at a rate of 2 min of arc/min with a 10-sec time constant. a, February 26, 1966; b, March 4, 1966; and c, March 12, 1966.

\* 1 flux unit =  $10^{-26}$  W/m<sup>2</sup>/c.p.s.

Fig. 2. Measured values of the equivalent black-body temperature,  $T_{BB}$ , of Mercury as a function of the planetocentric phase angle,  $\theta$ . The solid curve is the best fitting sinusoidal curve  $T_{BB} = 238 + 75 \cos(\theta + 38)$ .

from one revolution to another and it may be expected that prolonged observations over many cycles and at several wavelengths will play an important part in determining the thermal properties of the surface of Mercury.

## Organic Molecules and the Coloration of Jupiter

BOTH naked eye and photographic observations of the visible surface of the planet Jupiter reveal the presence of regions of contrasting and variegated colours. The bands, belts and spots—particularly the Great Red Spot—exhibit characteristic coloration which must indicate differences in molecular composition from place to place at the level of the Jovian clouds. All spectroscopic searches for characteristic spectral features unique to a band, belt or spot have been negative. For example, the Great Red Spot appears spectroscopically as enhanced continuous absorption at short wavelengths with no other identifying spectral features at the resolving powers used. The variable appearance of the Jovian cloud coloration suggests that the molecules responsible are synthesized in certain locales, transported, and dissociated in other locales. Were the coloured compounds produced by a planet-wide thermodynamic equilibrium, the planet should show a generally uniform coloration. Micro-meteoritic infall should provide a small steady-state abundance of certain minerals; however, it seems highly implausible that such minerals would be differentially distributed over the clouds of Jupiter in such a way as to explain the coloration. A more plausible source of chromophores would appear to be the chief atmospheric constituents themselves, thus implying that the coloration is caused by the presence of organic matter at the cloud level of Jupiter<sup>1,2</sup>.

Hydrogen, methane, and ammonia are known to be constituents of the Jovian atmosphere. Because of the high cosmic abundance of oxygen, the impossibility of escape of atomic oxygen from contemporary Jupiter, and the low temperatures of the Jovian clouds, water is expected to be a chief constituent of the atmosphere below (and possibly near) the clouds. In an experiment in which Jovian conditions were simulated, a mixture of hydrogen, methane and ammonia was supplied with energy from a corona discharge producing such simple organic molecules as hydrogen cyanide, methyl cyanide, acetylene, ethylene and ethane<sup>3</sup>. Their interaction products were predicted to be brightly coloured. When water was added, aldehydes were also produced. In experiments relevant to the origin of life on Earth, mixtures of materials that are in effect simulated Jovian environments have been subjected to a wide array of energy sources and organic molecules have been produced in consistently high yield provided that the overall conditions are reducing<sup>4</sup>. Electrical discharges and solar ultra-violet light—which both lead to high electronic temperatures of the excited atoms and are to be expected in the vicinity of the Jovian clouds—will lead to the production of organic molecules by the thermodynamic equilibrium processes at high temperatures and subsequent quenching.

With the pressures, temperatures, and atomic composition prevailing at and below the Jovian clouds we have calculated with an electronic computer the expected distribution of molecular species under local thermodynamic equilibrium<sup>5</sup>. We find that because of the great excess of hydrogen, even such simple organic molecules as ethane are present with volume mixing ratios  $\leq 10^{-15}$ ; with strict thermodynamic equilibrium the coloration of the Jovian clouds cannot be explained by organic molecules.

We have found, however, that with high local temperatures and quenching there is a wide range of pressures and temperatures in which substituted benzene rings and polycyclic aromatic compounds are formed in significant yield. Two sample systems are displayed in Table 1. The first, at a pressure of 1 atmosphere and a temperature of 1,500° K, is intended to represent electrical discharges in the vicinity of the visible clouds; the second, at 10<sup>-8</sup> atmosphere and 1,000° K, is intended to represent a hypothetical Jovian thermosphere from which complex organic molecules rapidly diffuse to lower altitudes. In the former case, by far the most abundant compounds synthesized according to our calculations are just the compounds preferentially produced in the laboratory by corona discharge in the Jovian simulation experiments of Sagan and Miller<sup>3</sup>. In these sample calculations brightly coloured compounds (such as azulene, asphalt and azobenzene) are synthesized, as had also been predicted. More recently, experiments have been performed by Ponnampuruma<sup>6</sup> involving corona discharge in anhydrous mixtures of methane and ammonia at low temperatures. He finds that a reddish-brown polymeric material is

The formation of graphite was excluded. High temperatures produced by lightning could permit approach to such equilibria, followed by rapid quenching. Polynuclear aromatics and coloured compounds such as azulene tend to form.

synthesized by reaction between cyanides and hydrocarbons, a result consistent with the conclusions of the present paper. Similar results have been obtained by Lippincott and Pratt<sup>7</sup>, using a plasma discharge of radio frequency. Under conditions consistent with the thermodynamic calculations, bright yellow mixtures of unsaturated high molecular weight compounds form. Specific compounds identified include pyrene, coronene and chrysene. The first two of these compounds are yellow, while the last has a red-blue fluorescence. Thus equilibrium thermodynamics alone tends to produce complex organic molecules—some of them highly coloured—provided that high temperature occurs locally and intermittently.

### The Mundrabilla Meteorite: a New Discovery in Western Australia

In March 1966, while engaged on a geological survey of a portion of the Eucla Basin in Western Australia, we discovered two large iron meteorites. The two principal masses, lying some 600 ft. apart, are located on the Nullarbor Plain, to the north of the Transcontinental Railway (latitude 30° 47' S., longitude 127° 33' E.). Earlier reports of the sighting of a meteorite by a rabbit-trapper, now deceased, have led to several expeditions which failed, however, to discover these masses.

Fig. 1. Large mass of the Mundrabilla Meteorite, showing "basal" surface and "parting" surface.

Fig. 2. Large mass—close-up view of "parting" face showing knobby surface. A matchbox gives the scale.

Fig. 3. Smaller mass of the Mundrabilla Meteorite, showing ablation "furrows" with the "parting" surface to the left of the picture.

Field estimates indicate approximate weights of the masses to be 10 to 12 tons and 4 to 6 tons respectively. Both weights are considerably in excess of any previously recorded Australian discoveries.

The masses lie within slight depressions in clayey soil which overlies Nullarbor Limestone of Miocene age. Excavation has revealed the presence of an underlying irregular crust of finely laminated iron "shale", which rests directly on silicified Nullarbor Limestone. Similar fragmentary iron shale also occurs in an incomplete stellate pattern, distributed for many hundreds of feet, largely eastwards of both masses.

The larger mass tends to have a crude conical to hemispherical shape with the nose partially buried in the soil. In the present position of rest the axis is inclined at an angle of approximately 60° (Fig. 1).

Evidence of fragmentation of a larger mass is afforded by a sharp, angular, vertical face on the larger mass, which matches both in size and shape a similar sharp face on the smaller mass. Another parallel incipient fracture is apparent on the "basal surface" of the larger mass (Fig. 1).

The surfaces of each mass present an extremely "knobby" appearance (Fig. 2), presumably where troilite grains have been selectively ablated during passage through the atmosphere. Atmospheric weathering has undoubtedly modified these features although ablation furrows and striations are still well preserved and provide remarkably clear evidence of stable orientation in passage through the Earth's atmosphere (Fig. 3). Concentrations

of small iron fragments around the bases of each mass are presumed to have weathered from the larger masses since the fall.

The material of several of these smaller fragments has been shown by polishing and etching to belong to the medium-octahedrite subdivision of the iron meteorites. Large troilite grains together with irregular masses of graphite and (?) schreibersite are also present.

By means of a detailed grid of an area of several acres around the larger masses the distribution pattern of small iron and iron-shale fragments has been established. Preliminary investigation of the results indicates that the meteorite came from the west at a relatively low velocity and high angle. No evidence of cratering or bouncing was found and it appears that the meteorite parted from its smaller fragment before impact with the Earth's surface. The process of burning apart along one of two parallel fractures by the torch-like effect of concentrated air-channelling has abraded a great number of smaller fragments, which are distributed along a west to east band for at least 1 mile.

The area of the fall has an extremely arid climate, only a very thin soil cover and is one of very flat terrain with little or no drainage features. Consequently, the present find represents an extremely well preserved record of the fall of a large iron, from which much valuable information in many aspects of meteoritics may be gained.

We thank the managements of Beach Petroleum N.L. and Geosurveys of Australia Pty., Ltd., who have made possible the visits to the area and thus the collection of field data. We also thank Prof. A. R. Alderman and the Meteorite Advisory Committee of Western Australia.

### Some Geophysical Observations on the Great Glen Fault

EARLIER geologists<sup>1-3</sup> have considered the Great Glen fault as a normal or dip-slip fault, while Kennedy<sup>4</sup> interpreted it as a strike-slip fault, basing his view chiefly on a lithological similarity between the Strontian and Foyers granitic complexes, and he suggested that the former has been moved 65 miles south-west along the Great Glen fault. Shand<sup>5</sup> has not found such characteristic features of strike-slip faults as slickensides or friction-grooves and mylonite. Collette<sup>6</sup> thinks that the fault passes to the south-east of the Shetland Islands. Flinn<sup>7</sup> has examined the submarine topography of the Moray Firth and has outlined a possible course of the fault. Wilson<sup>8</sup> joins the Great Glen fault to the Cabot fault of North America. Riddihough<sup>9</sup> has conducted a detailed magnetic survey off the north coast of Ireland and suggests the presence of two faults which may have some relation to the Caledonian fault systems of Scotland.

The present communication briefly presents the results of a geophysical study of the Great Glen fault<sup>10</sup>. A study of historical earthquake records together with the instrumental determination of seismic epicentres shows three active centres along its length at each of which there has been repeated activity since 1768. All the epicentres except two lie on the southern side of the fault. The Inverness area appears to be the most active region, but no earthquake has been reported since 1934. The region near Fort William has become active since 1924. A probable westward continuation of the fault is suggested by the submarine contours in the region, and the continuation

and the submarine contours are shown in Figs. 1 and 2, respectively.

A survey of the total magnetic field intensity and vertical magnetic field intensity of the fault has indicated magnetic anomalies of deep seated origin over the Strontian and Foyers granitic complexes. Fig. 3 shows the anomalies of total magnetic intensities. The total magnetic anomaly of the Foyers granitic complex is approximately elliptical in plan and seems to reflect the general shape of the granitic complex. It has the steepest gradient towards the north. The maximum amplitude of the

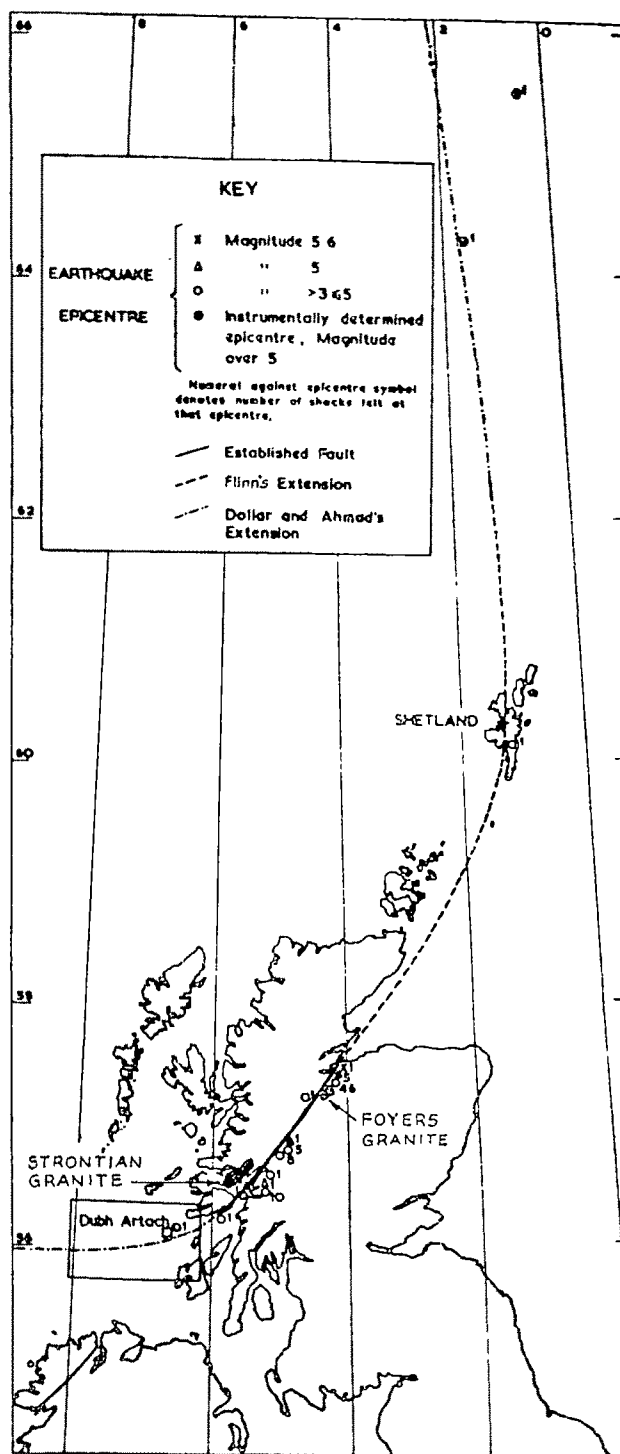

Fig. 1.

Fig. 2. Submarine contours showing the western extension of the Great Glen fault. Scale: 1 in. = 18 miles.

anomaly is 440 gamma and nearly half of the granitic complex is enclosed by 400 gamma contours. On the basis of the magnetic anomaly, it is suggested that the Foyers granitic complex is a stock-like intrusion about 2 miles wide and 8 miles long, extending to a depth of about 13 miles with the strike of its major horizontal axis N50E, and the stock is deduced to lie well to the south-east of the Great Glen—south of Loch Mhor. The contours of the Strontian total magnetic anomaly also follow the shape of the granitic complex and the steepest gradient is towards the west. The maximum amplitude of the anomaly is 350 gamma and nearly half of the complex is surrounded by 200 gamma contours. One of the probable interpretations of the anomaly is that the Strontian granitic complex is a separate intrusion of a stock-like form about 4 miles wide and 8 miles long extending to a depth of about 13 miles with the strike of its major horizontal axis nearly north-south and its stock is centred south of Kingairloch. Magnetic bodies can extend only to a certain depth in the Earth's crust and 13 miles is considered to be the maximum depth to which matter can remain magnetic. The stock may be deeper than 13 miles, but its real depth cannot be detected by the magnetic anomaly.

By the help of Vacquier<sup>11</sup> theoretical magnetic models in which the direction of magnetization is assumed in the Earth's main magnetic field, susceptibility contrast is determined, and the values are 0.0054 and 0.0023 for the Foyers and Strontian granitic complexes, respectively. The values are rather high. Thirteen thin sections from the Strontian and Foyers complexes were examined, and from them it is observed that the Foyers complex has twice the volume of magnetite than the Strontian complex has. Mould<sup>12</sup> has reported higher values of ferric and ferrous oxide for the Foyers complex compared to the values for the Strontian complex<sup>13</sup>.

A radioactivity field survey has revealed that the Strontian granitic complex has an average natural gamma radiation of about 6  $\mu$ r./h as compared to the Foyers granitic complex of about 3  $\mu$ r./h. No significant change in radioactivity was found to occur between the three members of either the Strontian or Foyers complex. Results

of a laboratory radiometric assay give an average for the Strontian complex of 31 p.p.m. (equivalent octuranium trioxide) as compared with 25 p.p.m. for the Foyers complex.

Foyers granitic complex is more magnetic and less radioactive as compared with the Strontian. Both intrusions extend down to a depth of about 13 miles and have separate stocks and different strikes. Munro<sup>14</sup> has reported structural differences between the two complexes. On the basis of available geophysical and geological evidence, it is considered improbable that the Strontian granitic complex is a part of Foyers, thereby throwing doubt on Professor Kennedy's postulated horizontal displacement of these masses by about 65 miles.

It is postulated that a stress pattern with a dominant vertical component was brought into being at the time of, or as a result of, the 'Newer Granite' intrusions, which gave rise to the Great Glen fault. The seismic and geological evidence is consistent with the dip-slip movement on the fault.

## PHYSICS

### Does a Moving Body appear Cool?

P. T. LANDSBERG in an interesting note<sup>1</sup> suggests that the "true" value of temperature of a moving body at relativistic speeds will appear to be the same as the temperature measured in the inertial frame of the body itself. He reaches this conclusion by re-defining temperature in terms of entropy and of internal energy.

I would like to suggest that the whole concept of the apparent temperature of a moving body needs some physical consideration before any mathematics are employed at all.

Suppose that the moving body consists of a box containing gas at about 0° C temperature. Then, if this gas is observed as it moves rapidly past a stationary observer, it will, as is well known, suffer a Fitzgerald-Lorentz contraction in the direction of motion by an amount of  $\sqrt{1-w^2/c^2}$  or  $1/\beta$ , where  $w$  is the velocity of the box with respect to the observer. We know, also, that time measured in the box will move more slowly than time as measured by the observer, the same factor being involved.

This means that if we consider any individual molecule in the gas in the box which happens to be moving in the direction of motion of the box, its velocity will appear to our observer to be reduced by a factor  $\beta^2 \times$  the measurement made relative to the box itself, because the distance which the particle moves between two collisions or other events will be reduced and the time between them increased as seen by the observer.

On the other hand, a molecule moving transversely to the box will appear to the observer to cover exactly the same distance relative to the box between two events, in the  $\beta \times$  increased time, so that in this case its apparent velocity is reduced only  $\beta$ -times.

We have thus, in the view of the stationary observer, a set of particles in the box with a distribution of velocity in one direction quite different from that in the two transverse directions, and any arguments about temperature, which is normally taken to refer to isotropic motions at least in a gaseous system, will be very difficult to apply. The mass of each particle will, of course, appear to be increased  $\beta$ -times to the observer in whatever direction the particles are moving, but nevertheless the mean relative kinetic energy of the particles will appear to be reduced, even if moving transversely.

On the simplest definition of temperature, therefore, the body will indeed look cooler as a result of its motion, even though the question of how much cooler may be regarded as ambiguous. Temperature could, of course, be defined in a number of ways and doubtless each of these

would give a different answer to the apparent change in relativistic conditions, because, as I have tried to show, the whole idea of temperature must be changed drastically when considering such fast moving bodies.

On the general principle that the simplest definition is best, Einstein's original expectation that a moving body would appear to be cool would seem qualitatively valid, while Professor Landsberg's case would seem to be only a selected example of a very much larger class of less simple definitions.

## THE SOLID STATE

### Fatigue Crack Propagation in Metals

A RECENT paper by Pearson<sup>1</sup> reports the results of crack propagation experiments on various metals, of which Young's moduli  $E$  range from  $6.5 \times 10^6$  lb./in.<sup>2</sup> to  $30 \times 10^6$  lb./in.<sup>2</sup>. It was found that the fatigue crack propagation rates were sensibly equal when the applied stress  $f$  was a fixed proportion of  $E$ . I have recently obtained theoretical support for this from the (static) analysis of the stresses in the neighbourhood of a crack in a perfectly elastic sheet. Account is taken of the varying geometry of the crack and it is shown, for example, that near the tip of the crack

$$\frac{1}{E} \sigma_y \sim \frac{1}{2} \ln \left( \frac{2f^2 c}{E^2 x} \right)$$

where  $x$  is measured from the tip and in line with the crack,  $2c$  is the length of the crack, and  $\sigma_y$  the direct stress normal to the line of the crack. The important points to notice from this equation are that the stresses are not proportional to the applied load and, furthermore, they depend on the value of Young's modulus itself. A measure of the extent of the stress singularity is given by equating to unity the terms in parentheses, whence

$$\bar{x}, \text{ say} = \frac{2f^2 c}{E^2}$$

The significance of the parameter  $\frac{f}{E} \sqrt{c}$  follows immediately from the assumption that the crack propagation rate depends primarily on the distance  $\bar{x}$ .

### Amorphous Nucleation in Metals

EVIDENCE from metal films grown inside electron diffractometers suggests that the earliest stage of film growth, when metals are deposited on amorphous substrates, is the formation of completely disordered clusters of atoms. In face-centred cubic metals the average thickness for this stage of growth is less than 10 Å, but with some body-centred cubic metals<sup>1,2</sup> the amorphous phase persists to thicknesses more than 50 Å.

After the initial stage, growth can be interpreted from theoretical calculations of the elastically diffracted intensity profiles<sup>3-6</sup>. Fig. 1 shows these for cold lead, assuming randomly oriented identical parallelepipeds<sup>6</sup> each of  $n^3$  atoms;  $2 \leq n \leq 9$  in the successive curves. Fig. 2 shows another process leading to "normal" face-centred cubic diffraction patterns. Here the profiles due to 27-atom and 729-atom assemblies are combined and well developed patterns are reached when most atoms are rearranged in the larger crystals. A combination of the two kinds of process can account for the growths observed<sup>5</sup> after the initial stage.

In gold, silver, 80/20 nickel-iron alloy, nickel and lead, however, the earliest profiles recorded have only three peaks in the range  $0.5 < sa < 4.5$  and these simple profiles cannot be fitted to the profiles of 4- or 8- or 13-atom assemblies because the first ring is too sharp. Profiles of very similar shape are observed in X-ray or neutron diffraction from monatomic liquids<sup>7</sup>.

It is possible to compare the elastic electron diffraction profile of a molten face-centred cubic metal with the profiles observed at the earliest stages of vapour deposited growth, and Fig. 3 shows this comparison for lead. The curve *a* is for liquid lead about 50 Å thick, that of *b* the first stages of a growth leading to the formation of a polycrystalline lead film. The data are scaled to the same relative intensity of the first ring, and plotted on a base of  $sb$ , where  $b$  is the nearest neighbour spacing of the crystalline lattice. The curves *a* and *b* are nearly identical except for a shift outwards of *b* (implying a shorter nearest neighbour spacing). Curve *c* is the earliest stage of a silver growth, leading in the usual way to a polycrystalline diffraction profile. Curves *a*, *b* and *c* are taken from well filtered measurements and the background scattering from the support film of amorphous carbon has been subtracted—an approximation which can be justified with these specimens. Curve *d* is an unfiltered profile of

Fig. 1. Development of the theoretical differential scattering cross-sections of lead films consisting of uniform randomly oriented micro-crystals, as the size of crystal is increased. The data for  $f^2$  are taken from the *International Crystallographic Tables*, 3, 1962, and are based on the Thomas-Fermi-Dirac statistical model; interference functions are from (6).  $a$  = face-centred cubic lattice spacing,  $s = 2 \sin \frac{1}{2} \beta / \lambda$ . Successive curves are displaced upwards.

Fig. 2. Development of the theoretical diffraction profile of lead by conversion of 27-atom crystals into 729-atom crystals.

Fig. 3. Electron diffraction profiles of liquid lead (*a*), and of early stages of lead (*b*), of silver (*c*), and of iron (*d*), grown *in situ* in a scanning electron diffraction system. Different diffractometers were used for (*a*), for (*b*) and (*c*), and for (*d*). (*a*), (*b*) and (*c*) are well filtered profiles. The curves are normalized to the inner peak and the dimensionless parameter  $(sb) = 2 \sin \frac{1}{2} \beta / \lambda \times$  nearest neighbour spacing.

amorphous iron (with filtered data the inner ring is sharper).

The profiles *b*, *c* and *d* are closely similar in form to that of the liquid *a*, when plotted against the appropriate dimensionless parameter,  $s \times$  (the nearest neighbour spacing),  $b$ . The values of  $b$  at 20° C (ref. 8) are shown in Table 1; they cover a considerable range. This fact is evidence that the profiles are not due to unknown compounds formed by interaction between residual gas or substrate atoms and the first deposited atoms of the metals.

Table 1 also gives the values of  $sb$  for the inner ring, which have a spread of  $\pm 5.3$  per cent about the median value of 1.22. The spread may result in part from uncertainties in the calibration of the patterns, which was done from the actual specimen when cooled or when fully developed. With curve  $a$  the calibration is from the crystalline phase at an unknown temperature difference from the melt; and in all the curves the lattice spacing value of the calibration may differ slightly from the value taken, that of bulk metal. The important point, however, is the similarity of the profiles.

Table 1. VALUES OF  $b$  AND OF  $sb$  FOR THE INNER RING

Specimen	$b$ (20° C) <sup>a</sup> (Å)	$sb$
$a$	—	1.15
$b$	3.50	1.24
$c$	2.89	1.28
$d$	2.40	1.16

Since scattering differential cross-sections of this form are observed in the initial stages of film growth of many face-centred cubic metals and a number of body-centred metals, one may therefore conclude that the earliest stage of nucleation of metals on to amorphous substrates is clusters of atoms which are amorphous in the strict sense of the disorder characteristic of monatomic liquids.

## CHEMISTRY

### Effect of Moisture on Liesegang Ring Formation in Ammonia-Hydrogen Chloride System

IF ammonium chloride is formed by counter-current diffusion of ammonia and hydrogen chloride gases in a long tube, periodic precipitation of the product in the form of rings is observed. This phenomenon has been explained by considering that nucleation and deposition of the product occur only when conditions of supersaturation exist, that is, when the concentration product of the reactants greatly exceeds the solubility product of ammonium chloride. By using this concept of supersaturation, Wagner<sup>1</sup> has developed a mathematical model which accounts for the formation of the "Liesegang rings" and which predicts accurately the frequency and separation of the rings.

Uncertainty arises, however, as to the importance of the presence of water vapour in the nucleation of the solid and formation of the rings. Hedges<sup>2</sup> predicted that Liesegang rings could be formed in this system in the absence of water vapour, while Johnston and Manno<sup>3</sup> expressed a contrary opinion. Spatz and Hirschfelder<sup>4</sup> generated the ammonia and hydrogen chloride from their aqueous solutions and postulated that nuclei were formed in the gas by clusters of reactant molecules of not less than a certain critical size, approximating to 100 molecules. Reaction between the molecules in the cluster was assumed to occur instantaneously.

We have investigated the effect of water vapour on the formation of Liesegang rings and its effect on the particle size distribution of the product formed. Initially, the reaction of ammonia and hydrogen chloride under moisture free conditions was investigated. The gases were passed through calcium chloride or phosphorous pentoxide

Fig. 1.  $a$  Counter diffusion of 5.12 per cent dry hydrogen chloride in nitrogen and 4.95 per cent dry ammonia in nitrogen in a 6-mm glass tube after exposure to air at 25° C, 75 per cent humidity.  $b$  and  $c$ , Liesegang rings formed by the interaction of ammonia and hydrogen chloride vapours in equilibrium with aqueous solutions at 30° C.  $b$ , 12.26 per cent w/w ammonia with 30.15 per cent w/w hydrogen chloride in an 8-mm glass tube.  $c$ , 14.91 per cent w/w ammonia with 26.15 per cent w/w hydrogen chloride in a 6-mm glass tube.

and molecular sieves. No Liesegang rings were formed, but when the tube was opened to a controlled atmosphere containing water vapour rings were successively formed as the water vapour diffused along the tube (Fig. 1a).

In the second series of experiments where the reacting gases contained water vapour, Liesegang rings formed along the tube (Fig. 1b and c) and the ring frequency and separation were in agreement with those predicted from Wagner's theory. The presence of water vapour is therefore essential for nucleation of the ammonium chloride and formation of Liesegang rings in this system.

## Kinetics of Low Temperature Oxidation of Coal and Char

At temperatures below 300°C the rate of oxidation of coal and char decreases with increasing time of oxidation, or alternatively with increasing extent of oxidation. Two types of equations have been widely used to represent the experimental curves relating the rate of oxygen uptake  $dq/dt$  to the time  $t$  or the total uptake  $q$

$$\text{Schmidt and Elder}^1, dq/dt = Dt^E \quad (1)$$

$$\text{Elovitch type}^2, dq/dt = F \exp Gq \quad (2)$$

where  $D$ ,  $E$ ,  $F$  and  $G$  are constants for a given set of experimental conditions. Carpenter and Sergeant<sup>3</sup> have observed deviations from the Elovitch type equation and suggested that they result from fresh sorption sites being created by the evolution of the gaseous oxidation products during the oxidation of coal.

Recent work at the Coal Research Establishment on the rate of oxidation of binderless char briquettes made from a low rank coal has shown that neither the Schmidt-Elder nor the Elovitch equation fitted the kinetics curves. The failure of the Elovitch equation is shown by the departure of the experimental points in Fig. 1 from straight lines. The curves shown are derived from a fresh theoretical treatment of the problem as follows.

The rate of oxidation of a char briquette is increased merely by interrupting the oxidation and maintaining the briquette at the same temperature in the absence of oxygen before further oxidation. This suggests that during isothermal oxidation, certain active sites in the char are deactivated by the formation of a surface-oxygen complex and then reactivated by thermal decomposition of the complex. The rate of oxidation decreases with oxygen uptake until it reaches a limiting value at which the rates of deactivation and reactivation are equal.

A theoretical equation for the rate of oxidation can be derived on this basis if certain assumptions are made concerning the dependence of the rates of oxidation, deactivation and reactivation on the number of active sites. Taylor and Thon<sup>4</sup> have discussed the derivation of the Elovitch equation in the kinetics of chemisorption, and have shown that it is consistent with the assumptions that the rate of sorption is proportional to the number ( $n$ ) of active sites remaining, and that the rate of deactivation of active sites is proportional to  $n^2$ . For the present purpose we have adopted the same assumptions for the rates of oxidation and deactivation; we have in addition postulated that the rate of reactivation of sites by thermal decomposition of the oxygen complex is proportional to the number of occupied sites.

These assumptions can be expressed in the following equations, in which the notation is derived from Taylor and Thon:

$$\text{Rate of oxidation} = dq/dt = an/n_0$$

$$\text{Rate of deactivation} = (dn/dt)_1 = -\alpha n^2/n_0$$

$$\text{Rate of reactivation} = (dn/dt)_2 = \beta(n_0 - n)$$

and thus we find

$$\frac{dq}{dt} = A + \frac{AB(A+2B) \exp - \gamma t}{(A+B)^2 - B^2 \exp - \gamma t} \quad (3)$$

where  $A = (\gamma - \beta)/2\alpha$

$$B = a - A$$

$a$  = initial rate of oxidation

$$\gamma = \sqrt{\beta^2 + 4\alpha\beta}$$

The rate of oxidation thus decreases from  $a = A + B$  when  $t = 0$  to a limiting value  $A$  when  $t \rightarrow \infty$ .

With a suitable choice of parameters it is possible to fit the experimental data to within the limits of error

Fig. 1. Experimental and calculated oxidation rates in air of binderless char briquettes. —, Calculated; x, experimental 100°C; □, experimental 150°C; ■, experimental 200°C; +, experimental 250°C; ○, experimental 300°C.

as shown in Fig. 1. On the other hand, the data can be fitted equally well by the equation

$$dq/dt = A^1/(1 - B^1(\exp - \phi t)/(A^1 + B^1)) \quad (4)$$

for which, however, we have been unable to provide a theoretical derivation. Although equation (3) may be preferable for fundamental investigations, it is awkward in form for practical use. Equation (4) and its equivalent

$$dq/dt = A^1 + B^1 \exp(-\phi q/A^1) \quad (5)$$

have therefore been used in the computation of oxidation rates after various time and amounts of oxygen reacted.

## BIOCHEMISTRY

### Mitochondria and pH

THE concept of intracellular pH depends on the assumption that the cell is either not divided into compartments, or that the volumes of the compartments are large enough to contain a statistically meaningful number of hydrogen ions, the "intracellular pH" in this case being a mean of the pH values in the various compartments. While this may be valid for cells, the concept cannot necessarily be extended to very small intracellular compartments. This can be shown in the case of a mitochondrion of say 0.5μ diameter and 5μ length. The volume of this com-

partment would be approximately  $10^{-12}$  ml. At pH 7.0 the hydrogen ion concentration is nearly  $10^{-7}$  g ions/l., and thus the mitochondrion volume would contain  $10^{-7} \times 10^{-3} \times 10^{-12}$  g ions. If the Avogadro number is  $6 \times 10^{23}$ , then the mitochondrion will contain

$$\frac{6 \times 10^{23} \times 10^{-7} \times 10^{-3} \times 10^{-12}}{2} \text{ hydrogen ions}$$

that is, thirty ions.

Because of random thermal motion, however, the laws of physical chemistry are inaccurate within a probable relative error of the order  $n^{-1}$  where  $n$  is the number of ions or particles that co-operate to bring about the law. Thus in the case of the pH of a mitochondrial volume the probable error involved at pH 7.0 will be  $(30)^{-1}$ , that is, 18 per cent.

There has been considerable discussion<sup>1-4</sup> of the function of "mitochondrial membrane pH gradients" in oxidative phosphorylation, and such a gradient has recently been reported as measured<sup>5</sup>. Claims have also been made for measuring intramitochondrial pH changes of 0.02 and less<sup>6</sup>. In this case it can be seen that the number of hydrogen ions involved in such a change would be too small to have any significance (approximately half a hydrogen ion).

I thank the Medical Research Council for its generous financial support.

### Effect of Prednisolone on Synthesis of DNA and RNA by Human Lymphocytes *in vitro*

THE ability of the extract of *Phaseolus vulgaris*, phytohaemagglutinin, to initiate the synthesis of ribonucleic acid (RNA), deoxyribonucleic acid (DNA) replication and cytokinesis in human lymphocytes *in vitro* is well known<sup>1-3</sup>. It has recently been shown that the response of normal human lymphocytes to phytohaemagglutinin can be markedly altered by the serum which is used to bolster the culture medium<sup>1</sup>. Of the sera which markedly depressed this response, some were obtained from patients with lymphocytic diseases; of these, many were treated with corticosteroids. We decided, therefore, to investigate the effects of corticosteroids on these cultures. Accordingly, we have measured the *in vitro* responsiveness initiated in normal human peripheral lymphocytes in the presence of increasing doses of prednisolone-21-phosphate by phytohaemagglutinin.

The culture systems which were used have been described in detail elsewhere<sup>1,2</sup>. Normal human blood was obtained by venipuncture, heparinized and allowed to settle for 2 h. The plasma supernatant, rich in leucocytes, was withdrawn and the concentration of leucocytes was ascertained with a clinical haemocytometer. The desired number of cells was then sedimented and the pellet was resuspended in 0.05 per cent trypsin for 6-7 min. After sedimentation the cell pellet was resuspended in a modified Eagle's HeLa medium (EHM)<sup>4</sup> which had been supplemented with 10 per cent bovine serum to give a final concentration of  $1.0 \times 10^6$  cells/ml. The cell suspension was pipetted into 16 mm  $\times$  150 mm test tubes in 3.0 ml. aliquots. Standard solutions were prepared by dissolving 90-100 mg of phytohaemagglutinin-M in 5 ml. of triple

distilled water. One millilitre of this solution was taken as 1.0 U and 0.1 ml. containing 0.1 U of phytohaemagglutinin was added to the culture tubes. Control cultures received 0.1 ml. of triple distilled water. This dose has been shown to be optimal for induction of synthesis of both DNA and RNA in these cultures<sup>1,2</sup>. The cultures were then gassed with 5 per cent carbon dioxide in air and incubated on a slant of 4° at 37° C. After 48 h all cultures received 0.1 ml. of a solution of EHM containing  $3 \times 10^{-5}$  molar amethopterin and  $1.5 \times 10^{-3}$  molar adenosine. Sixteen hours later 0.1 ml. of a solution of EHM containing 30  $\mu$ g/ml. of 2-<sup>14</sup>C-thymidine (S.A. 3.66 mc./mmole) was added and left for 6 h to measure the incorporation into DNA. After each addition the cultures were regassed with 5 per cent carbon dioxide in air before being returned to the incubator. The cultures were collected by sedimenting the cells and extracting the acid insoluble residue by successive treatment with 10 per cent trichloroacetic acid, 80 per cent ethanol, and a mixture of absolute ethanol and diethyl ether (1:1)<sup>1</sup>. The dried residue was taken up in 0.5 ml. of 90 per cent formic acid and 0.2 ml. were added to 20 ml. of  $\alpha$ -naphthylphenyloxazole for counting in a liquid scintillation spectrometer<sup>5</sup>.

To measure synthesis of RNA the cultures were planted in the absence of phytohaemagglutinin. After 42 h of incubation to allow endogenous RNA synthesis to diminish to a basal level<sup>2</sup>, 0.1 ml. of triple distilled water or phytohaemagglutinin (0.01 U) was added to the cultures. Twenty-four hours later the cultures were pulsed for 2 h with 0.1 ml. of an EHM solution containing 1.39  $\mu$ g/ml. (<sup>3</sup>H) cytidine (S.A. 2.34 c./mmole). The cultures were then collected and treated as described above.

Prednisolone-21-phosphate was diluted with triple distilled water and added to the cultures in 0.1 ml. aliquots to give final concentrations of 0-1,000  $\mu$ g/culture. Both RNA and DNA were measured as described after the addition of prednisolone-21-phosphate at the time of planting. Synthesis of RNA was also measured after adding prednisolone-21-phosphate at the same time that the phytohaemagglutinin was added. The results of these experiments are shown in Figs. 1 and 2. It is seen that 0.01  $\mu$ g/culture of prednisolone-21-phosphate had only a minimal effect on the response; however, further increases in dosage effected a logarithmic dose-related suppression of replication of DNA. Inhibition of synthesis of RNA by prednisolone-21-phosphate also occurred at 0.01  $\mu$ g/culture and was logarithmically dose-related up to 100  $\mu$ g/culture. When the addition of prednisolone-21-phosphate was delayed to the time at which the cultures

Fig. 1. The effect of prednisolone-21-phosphate on incorporation of labelled thymidine. Normal human lymphocytes were cultured as described in the text and results were expressed as log counts/min/culture versus log dose of prednisolone-21-phosphate. The percentage response is also shown.

Fig. 2. The effect of prednisolone-21-phosphate on incorporation of ( $^3\text{H}$ ) cytidine. Normal human lymphocytes were cultured as described in the text and results were expressed as log counts/min/culture versus log dose of prednisolone-21-phosphate. The percentage response is also shown. —●—, Prednisolone added at time of planting the cultures. —○—, Prednisolone added after 48 h of incubation, immediately after phytohaemagglutinin was added.

received phytohaemagglutinin, there was less inhibition of the response until a concentration of about 100–1,000  $\mu\text{g/culture}$  was reached. There was no incorporation of label into the cultures which did not receive phytohaemagglutinin.

Our data raise the possibility that the decline in number of blood lymphocytes after treatment with corticosteroids<sup>6,7</sup> may result in part from a decrease in the replication of lymphocytes. It has been reported that hydrocortisone will inhibit transformation in mixed lymphocyte cultures<sup>8</sup>. Other investigators have observed that 100  $\mu\text{g/ml.}$  of prednisolone will prevent transformation and 0.01  $\mu\text{g/ml.}$  will prevent mitosis of lymphocytes stimulated by phytohaemagglutinin<sup>9</sup>. It is noted here that a dose as low as 0.003  $\mu\text{g/ml.}$  begins to suppress the synthesis of RNA and DNA. Accordingly when serum from patients ingesting corticosteroids is used to bolster medium in investigations of the response of lymphocytes to phytohaemagglutinin, the potential effects of the concentration of corticosteroid in serum must be considered, because very small concentrations will interfere with synthesis of DNA and RNA.

## Extension of the Concept "Vertebrate Epidermal Melanin Unit" to embrace Visceral Pigmentation and Leucocytic Melanin Transport

THE process described by Masson<sup>1</sup> as "cytochrome" implies that the melanocyte is the active partner in the transfer of melanin granules to Malpighian cells. Cruickshank and Harcourt<sup>2</sup> pointed out this implication and advanced evidence that, as judged by the activity of the cell membrane, the epithelial cell appeared to play a more active part in the transfer of melanin granules. Recent investigations indicating that the Malpighian cells may be the active partner in phagocytosing melanin granules led Fitzpatrick and Breathnach<sup>3</sup> to the development of their concept of an "epidermal melanin unit" in which the functional unit of pigmentation is seen as a melanocyte and the pool of epidermal cells to which it is connected. Such units were recently demonstrated in amphibian skin by Hadley and Quevedo<sup>4</sup>, who in addition provided evidence that the rate at which melanin granules are carried away from melanocytes may also be a decisive factor in determining the rate at which they are synthesized. This useful concept is a significant advance in the study of "melanokinetics"<sup>5</sup>, but it does not embrace other cells transporting melanin, such as leucocytes.

Leucocytic melanin transport received much attention up to the end of the nineteenth century<sup>6</sup>, but the observations could not be interpreted before identification of melanocytes as the cellular site of melanogenesis<sup>5</sup>. In view of increasing awareness of visceral melanin deposits<sup>7,8</sup>, leucocytic melanin transport<sup>5,9-11</sup> again assumes importance.

In acute aseptic cutaneous inflammatory reactions of Bantu and Cape Coloured individuals, the first neutrophils to appear clumped melanin granules and these were transferred to lymphocytes which subsequently hypertrophied to macrophages<sup>9</sup>. "Dendritic processes" were frequently seen in this transport (Figs. 1 and 2), but in well filled macrophages vacuoles were common and "dendritic processes" were never seen (Fig. 3).

This transport of melanin was very marked in hyperpigmented individuals, but inconspicuous in Caucasians<sup>9</sup>. In Caucasians with phenothiazine-melanos, however, leucocytic melanin transport could be confirmed<sup>12</sup>.

In normal Bantu males, lymphocytes containing melanin were observed in concentrates of leucocytes from peripheral blood, but not in Caucasians<sup>10</sup>. This could also be observed in Caucasians with phenothiazine-melanos<sup>12</sup>.

The skin-draining lymph nodes in Bantu may show marked melanin deposits in 85–90 per cent of autopsies<sup>13</sup> while the incidence of such melanin deposits were found to be only 20–26 per cent of similar lymph nodes in Caucasians<sup>14</sup>. Melanin deposits in viscera were marked in autopsy series of patients with phenothiazine-melanos<sup>8,12,15</sup>; in both Negro and Caucasians deposits of

Fig. 1.

Fig. 2.

Fig. 3.

placental melanin were more frequent in cases with a history of skin injury during pregnancy<sup>16</sup>.

In amphibians especially, but also to a lesser extent in reptiles, leucocytes containing melanin are readily demonstrable in the peripheral blood, and visceral melanin deposits in liver, lungs, heart and kidney are conspicuous in amphibians<sup>10</sup>.

In hyperpigmentation associated with Addison's disease, hyperthyroidism and anorexia nervosa, an absolute lymphocytosis in the peripheral blood is common, and depends on changes in pituitary-adrenocortical function, which is also related to the increased pigmentation<sup>11</sup>. In Bantu and Caucasians, studied at sea level in an area free from malaria and where individuals were selected for normal haemoglobin concentrations and erythrocyte sedimentation rates, the Bantu had a statistically significant higher lymphocyte count and a statistically highly significant neutropenia as compared with the Caucasians. This would appear to depend on lesser adrenocortical activity in the Bantu<sup>11</sup>.

These observations suggest that, if the concept of an "epidermal melanin unit" is extended to all vertebrates justifying reference to a "vertebrate epidermal melanin unit"<sup>4</sup>, the leucocytic transport mechanism should be included. The function of leucocytes appears at present to be integrated with the unit as follows: (i) Disruption of epidermal melanin units, as in our experimental model<sup>9</sup>, allows leucocytes to assume a role in melanin transport. (ii) When epidermal melanin units are filled to capacity as in hyperpigmentation, whether racial or acquired, the leucocytic system apparently acts as an additional transporting system and could help to maintain the existing high rate of melanogenesis. (iii) Hyper-

pigmentation induced by hormones (Addison's disease, hyperthyroidism and anorexia nervosa) is also accompanied by an increase in the number of lymphocytes in the peripheral blood, which suggests that with increased melanogenesis, the additional transport system is simultaneously activated. (iv) The activation of the additional transport system is associated with increased visceral melanin deposition.

Phenothiazine-melanosis shows evidence of (i) increased melanogenesis<sup>15,17</sup>, (ii) leucocytic melanin transport<sup>12</sup>, and (iii) visceral melanin deposits<sup>15</sup>. It has been shown that melanin, as electron acceptor, binds with the electron donor chlorpromazine probably by the formation of charge transfer complexes<sup>18,19</sup>. These findings could be explained if the melanin accepting ability of cells depended on their concentration of electron donors. The transfer of granules would then stop on cancellation of the charge by the formation of charge-transfer complexes. Chlorpromazine as electron donor would thus enhance transfer to epidermal units and leucocytes, increase melanogenesis, and this would result in visceral melanin deposition.

The absence of hair and feathers, and the thin integument of amphibians, could limit the capacity of the epidermal component of the unit. Additional transport through leucocytes would then help to maintain the rate of melanogenesis and increase visceral melanin deposition. Such visceral melanin deposition renders a potent electron acceptor in tissues which may now be vulnerable to free radical formation by ultra-violet radiation as in the case of the skin<sup>20</sup>. The evolution to a thicker integument, leading to a larger epidermal component and enhanced by skin appendages as melanin repositories, would lessen the demand on the additional transport system.

### Lactic Dehydrogenase Isozymes: Changes during Lens Differentiation in the Chick

THE lens of the eye is an ideal system for the examination of cell differentiation because of its isolation from the blood stream, lack of connective tissue and because it includes only cells derived from ectoderm. Furthermore, with the epithelial cell, the annular pad cell and the cortical and nuclear fibre cell, the lens cell shows a sequence of progressive differentiation. The lens lacks a mechanism for discarding cells, and so has within its structure a complete record of its embryonic and adult differentiation.

The change in lactate dehydrogenase (LDH) isozyme pattern during the development of the whole chick lens has been described<sup>1</sup>. We have analysed the LDH isozyme pattern in correlation with the structural differentiation from epithelial to fibre cell, and at different stages of development.

Eyes were taken from 8, 12, 15, 18 and 19 day old White Leghorn chick embryos, newly hatched chicks, and from 1 day old, 10 day old, 3 week old, 6 week old, 7 week old and 1-2 year old animals. Whole lenses were dissected from surrounding tissues and homogenized in 0.9 per cent saline solution, using 100 mg wet weight of tissue/ml. of solution. The homogenates were centrifuged at 15,000*g* at 4° C for 25 min and the supernatant was used for enzyme analysis. Extracts were also prepared from epithelium, annular pad, cortical fibre and nuclear fibre cells. The lens was viewed under a stereomicroscope and the capsule anterior to the equator was excised circumferentially. The capsule with attached epithelial cells was homogenized in minimal amounts of saline. The annular pad was removed from the lens and homogenized using 100 mg wet weight of tissue/ml. saline. The most

superficial fibres were dissected as cortical cells and the core of the lens as nuclear fibre cells. Intermediate fibre cells were discarded. LDH isozymes were separated by vertical starch gel electrophoresis<sup>2</sup>. The gel was prepared with 0.076 molar *tris*-citrate buffer (*pH* 8.6), and boric buffer (5 g of sodium hydroxide, 37 g of boric acid in 2 l. of distilled water) served as bridge buffer<sup>3</sup>. After electrophoresis at 4° C for 16 h at a field strength of 6 V/cm, the gel was incubated in a medium composed of 45 mg of nicotinamide adenine dinucleotide, 37 mg of *p*-nitro blue tetrazolium salt, 3 mg of phenazine methosulphate, 113 ml. of distilled water, 15 ml. of 0.5 molar *tris*-hydrochloric acid buffer (*pH* 7.4), 7.5 ml. of 0.1 molar potassium cyanide and 15 ml. of 0.5 molar sodium lactate solution (*pH* 7.4). Enzyme activity was also measured on a spectrophotometer at 40° C, at a wavelength of 340 mμ (ref. 4). Pyruvate concentrations of  $3.3 \times 10^{-4}$  molar and  $6.6 \times 10^{-3}$  molar were used to detect the activity of, mainly, LDH 1 and LDH 5, respectively<sup>1</sup>.

The results are shown in Fig. 1. In the 12 day embryonic lens, LDH isozymes 3-5 predominate in epithelial and fibre cells. The nuclear fibre cells show less enzymatic

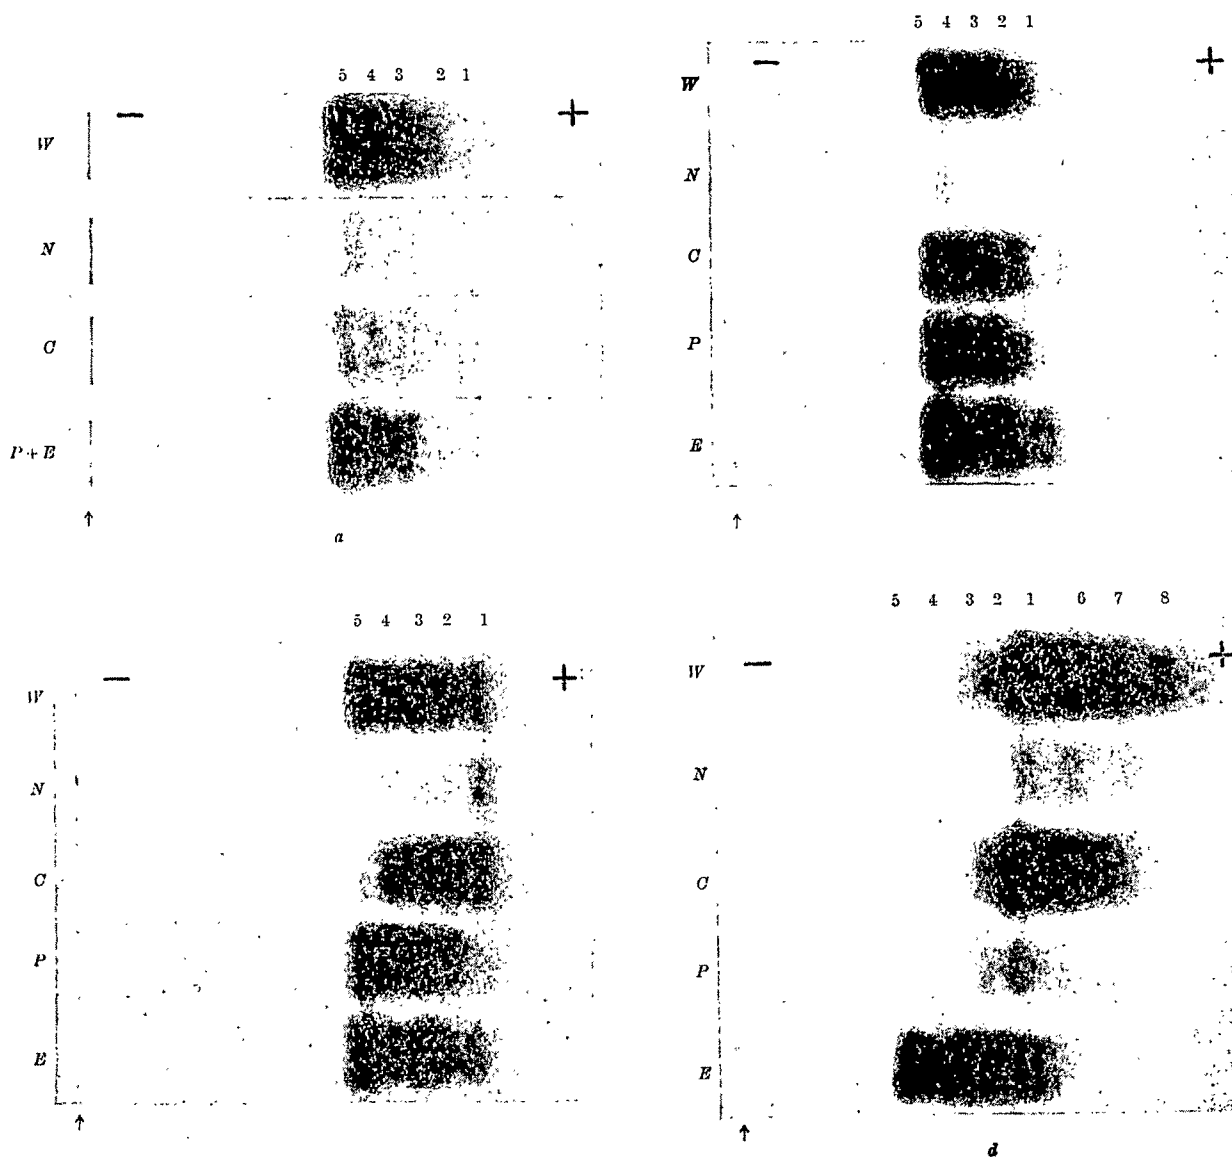

Fig. 1. Isozyme pattern of chick lenses of different ages. (a) 12 day old embryo; (b) 1 day after hatching; (c) 10 days after hatching; (d) 1 yr old adult. The arrows indicate the origin. W, Whole lens; N, nuclear fibre cells; C, cortical fibre cells; P, annular pad cells; E, epithelial cells.

activity of tissue than the cortical fibre cells or epithelial cells. A result of the isozyme distribution is that the 12 day embryonic whole lens shows a predominance of LDH isozymes 3-5. This isozyme pattern was maintained during the hatching period except for slight changes which consisted of an increase of activity at LDH 1 relative to the other isozymes. The epithelium acquires a characteristic isozyme pattern with maximal activity at LDH 5, 3 and 1, while the annular pad cells show a marked intensity at LDH 5 and 3, but not at LDH 1. Thus, the newborn whole lens shows a more uniform distribution of isozymes although LDH 5, 4 and 3 still predominate.

Within a few days of hatching there is an abrupt change in isozyme distribution. LDH 5 and 3 still predominate in the epithelial and annular pad cells of 10 day old chick lenses, but the fibre cells show a marked shift in activity, with heaviest staining at LDH 1 and not at LDH 3-5. Thus the whole lens shows markedly increased activity at LDH 1 over that found in embryonic lenses and LDH 1 and 5 stain with nearly equal intensity.

The isozyme patterns of older lenses show an increasing predominance of anodal isozymes. This is due to an increase of LDH 1 especially in the cortical fibre cells and to a lesser extent in the nuclear fibre cells. There is, at the same time, a progressive decrease of activity at LDH 5, 4, 3 and 2. Additional bands which appear on the anodal side of LDH 1 are found in large quantities only in the fibre cells and appear first in significant amounts in lenses of 6 and 7 week old chickens.

In the lens of 1 year old adult animals, LDH 5 and 3 are still mainly present in the epithelium, but in the annular pad there is a much decreased amount of LDH 5. The fibre cells show the heaviest staining at LDH 1 and the more anodal bands, but LDH 5 and 4 cannot be detected. Thus the whole lens isozyme pattern reflects activity mainly at LDH 1 and the more anodal bands, and only traces of LDH 5 and 3 are discernible. Epithelial cells comprise only a very small part of the total adult lens weight, and so their predominant isozymes, LDH 5 and 3, are greatly diluted in the whole lens extract.

Spectrophotometric analysis of LDH activity confirmed these observations, for LDH 1 acts maximally at low pyruvate levels and LDH 5 at high pyruvate levels. There is a marked increase in enzyme activity with age for the whole lens, cortical and nuclear fibre cells, especially at the low pyruvate concentration. In a 1 year old animal the ratio of activity at low pyruvate concentration to that at high pyruvate concentration was 1.5 for the fibre cells, and 0.85 for the epithelial cells. The annular pad cells showed maximal activity in the 7 week old animals, with more activity/g of tissue than the fibre cells.

We have provided here clear evidence of a biochemical change associated with the differentiation of the epithelial cell into a fibre cell, which is manifested only after hatching. There is no significant difference between epithelial and fibre cell isozyme patterns before hatching, so that the change in isozyme pattern of the whole lens from a predominance of cathodal isozymes in embryonic life to anodal isozymes in adult life is a function of a change in enzyme composition of the fibre cell. The epithelial cell pattern is essentially the same in embryonic and adult life.

Several theories have been proposed to explain the significance of isozymes and the changes in the pattern of distribution that occur during development. These relate to the aerobic or anaerobic nature of respiration<sup>5</sup>, to the presence or absence of a nucleus in the cell<sup>6</sup> and to the rate of mitotic activity<sup>7</sup>. These theories do not satisfactorily explain the change in lens isozyme pattern which occurs within a few days of hatching, and it seems most reasonable to assume that this change is related to metabolic factors, possibly in connexion with the onset of lens function.

### Lignin and Certain Other Chemical Constituents of *Phylloglossum*

*Phylloglossum drummondii*, Kunze is a small and relatively rare cryptogam of New Zealand and Australia. It is considered to be a lycopod which is reduced and specialized in the adoption of a geophytic habit<sup>1</sup>. So far as we know, it has not been examined for any of its organic chemical constituents.

In view of the fact that two types of lignin are known to occur in *Lycopodium* and that the distribution of these types is in agreement with suggestions regarding the taxonomy of the genus<sup>2</sup>, we considered it of interest to examine *Phylloglossum*, the only other generally accepted living genus in the *Lycopodiales*.

Through the kindness of Mr. W. E. Hillis, 1.2 g of air-dried *Phylloglossum* was made available to us. The main results of our chemical analyses were as follows:

(1) Alkaline oxidation of the extracted wood-meal with copper hydroxide yielded vanillin and *p*-hydroxybenzaldehyde as well as *p*-hydroxybenzoic, vanillic and syringic acids.

(2) Phenols, obtained by alkaline hydrolysis of ethanol insoluble residues, included protocatechuic, *p*-hydroxybenzoic, vanillic ferulic and syringic acid.

(3) As in *Lycopodium*, the chief sugars in aqueous or ethanolic extracts are sucrose, glucose and fructose.

(4) Alkaloids were detected but the limited amounts of material available precluded identification. Chromatograms showed that some of the alkaloid spots agreed in *R<sub>F</sub>* with those from a similar extract of *Lycopodium clavatum*. They differed in their chromatographic behaviour from the fifteen authentic *Lycopodium* alkaloids available to us.

Species of *Lycopodium* which are included in the genera *Lycopodium* and *Diphasium*, as proposed by Rothmaler<sup>3</sup>, yield syringic acid in ethanolic extracts or on lignin degradation whereas species included in the genera *Huperzia* and *Lepidotis* do not<sup>4</sup>. *Phylloglossum* therefore displays a chemical similarity to the latter groups. This may be of some significance in considerations of its phylogenetic relationships. The general absence of syringaldehyde from among the lignin oxidation products of *Phylloglossum* or of other lycopods is curious in view of the condition in *Selaginella*. In *Selaginella*, all species which we have examined so far yield both syringaldehyde and syringic acid on lignin degradation.

Paper chromatographic methods were used for the identification of sugars<sup>5</sup>, phenolic acids and phenolic

aldehydes<sup>2</sup>. Alkaloids were extracted from 0.8 g of plant material<sup>5</sup> and examined by thin layer chromatography on plates of silica gel G made up with 0.1 normal sodium hydroxide. The solvent systems were benzene:chloroform:methanol (8:1:2) and benzene:ethanol (5:6). Spots were visualized with the iodo-platinate reagent<sup>6</sup>.

We thank Dr. H. Ayer, University of Alberta, and Dr. D. B. MacLean, University of New Brunswick, for samples of *Lycopodium* alkaloids and the National Research Council of Canada for financial assistance.

### Dissociation and Recombination of a Polygalacturonase Complex during Ion Exchange Chromatography

PURIFICATION and characterization of extracellular microbial polygalacturonases depend on reliable techniques for separation. By ion exchange chromatography, six apparently distinct polygalacturonase components were separated from the culture filtrate of *Fusarium oxysporum* variety 'Lycopersici' on an anion exchanger<sup>1</sup>, and four polygalacturonase components were obtained from *Coniothyrium diplodiella* by similar methods on anion and cation exchangers<sup>2</sup>. We now report the existence of polygalacturonase complexes of different particle sizes and their interconversion during ion exchange chromatography.

Extracellular polygalacturonase was obtained from a shake-culture filtrate of *Fusarium oxysporum* variety 'Lycopersici' (Sacc.) Snyder and Hans. grown in modified Richard's medium<sup>3</sup> containing 1 per cent w/v pectin and adjusted to pH 5.0. After 6 days growth, the cultures were centrifuged and filtered through a 'Millipore HA' filter (0.45 $\mu$ ) to remove all fungal cells. The filtrate was dialysed for 18 h against running tap water and for 8 h against distilled water, concentrated to about one quarter of its original volume under reduced pressure at 30° C in a rotary evaporator, and then frozen until it was used. Polygalacturonase activity was estimated by a cup plate assay<sup>4</sup>, in which zones of enzyme action were linearly related to the logarithm of the concentrations of enzyme.

For anion exchange chromatography, coarse grade DEAE cellulose with an exchange capacity of 0.93 mequiv./g was regenerated by the method of Albersheim and Killias<sup>5</sup>, packed into a column 1.9 cm in diameter, 19 cm high, and equilibrated with 0.01 molar acetate buffer (pH 5.0). The concentrated culture filtrate was placed on the column and polygalacturonase was eluted with 200 ml. of buffer followed by 200 ml. of buffer containing 0.4 molar sodium chloride. Samples of 5 ml. were collected.

Of the total polygalacturonase obtained from the column, about 98 per cent was eluted by buffer immediately after the void volume, and 2 per cent, which was more highly adsorbed, came out with the mixtures of buffer and sodium chloride. Stepwise elution of similar columns with concentrations of sodium chloride below 0.4 molar has given several distinct components of polygalacturonase from the adsorbed enzyme of *Fusarium*<sup>1</sup>.

For cation exchange chromatography, 'Duolite CS-101' obtained from Bio Rad Laboratories as 'Bio-Rex 70', 100–200 mesh, 10.0 mequiv./g of dry wt, was regenerated according to the manufacturer's recommendations, packed into a column 3.0 cm  $\times$  30.0 cm, and equilibrated with 0.01 molar acetate buffer (pH 5.0). The concentrated culture filtrate was placed on the column and polygalacturonase was eluted in samples of 10 ml. by 200 ml. portions each of 0.01 molar and 0.1 molar acetate buffer (pH 5.0) and 1.0 molar sodium acetate. A similar elution schedule was followed by Endo<sup>2</sup>.

Almost all the polygalacturonase was adsorbed on 'Duolite CS-101', and was eluted as a single peak in 1.0 molar sodium acetate. Traces of polygalacturonase were detected in the 0.01 molar and 0.1 molar buffer eluates, but in total these represented less than 0.7 per cent of the enzyme eluted. Elution with intermediate concentrations of buffer and sodium acetate failed to give additional enzyme components.

The fractions which contained the highest polygalacturonase activity in 1.0 molar sodium acetate were combined, dialysed and rechromatographed on 'Duolite CS-101' and DEAE cellulose. Polygalacturonase rechromatographed on 'Duolite CS-101' as a single component corresponding to the original peak, and no enzyme was detected in the 0.01 molar and 0.1 molar buffer eluates. On DEAE cellulose, the 'Duolite CS-101' fraction chromatographed in a manner similar to the enzyme from the culture filtrate, that is, about 98 per cent of the polygalacturonase was eluted immediately after the void volume, while 2 per cent was adsorbed and eluted in 0.4 molar sodium chloride. Adsorption of polygalacturonase on DEAE cellulose indicates the presence of negatively charged enzyme molecules, which, theoretically, should not have been present in the component eluted from the cation exchanger, 'Duolite CS-101'. This deviation from the expected suggests that chromatography of polygalacturonase on DEAE cellulose can produce artefacts.

The relationship of polygalacturonase from the culture filtrate and the chief enzyme components obtained after cation and anion exchange chromatography was determined by gel filtration which permits fractionation of molecules according to their size. 'Sephadex G-200' was prepared for gel filtration according to the manufacturer's recommendations, packed in a column 2.5 cm  $\times$  35 cm and equilibrated with 0.01 molar acetate buffer (pH 5.0). Samples containing enzymes (2 ml.) were placed on the column; it was eluted with the acetate buffer, and 4 ml. fractions were collected and assayed for polygalacturonase activity.

Two distinct components of polygalacturonase were obtained from the culture filtrate (Fig. 1). The first component, eluted mainly in fractions 12–15, contained about 14 per cent of the total polygalacturonase obtained from the column and was probably composed of relatively large particles of enzyme, for molecules generally appear in the effluent which follows gel filtration in order of decreasing size. The main component, with smaller particles of enzyme, contained about 86 per cent of the polygalacturonase eluted.

The main component of polygalacturonase, eluted from a DEAE cellulose column immediately after the void volume, was applied to the column of 'Sephadex G-200'. Two distinct components of polygalacturonase were obtained which corresponded in the size of particles to those in the culture filtrate (Fig. 1). The component with the larger enzyme particles contained, however, about 1 per cent of the polygalacturonase obtained from the column, while the fraction with smaller particles of enzyme contained about 99 per cent of the polygalacturonase eluted. The small quantity (2 per cent) of polygalacturonase, initially more highly adsorbed by DEAE cellulose and thus removed from the main component, was insufficient to account for the relative loss of large particles of enzyme after chromatography on DEAE

cellulose. Dissociation of a complex between polygalacturonase, substrate molecules, and (or) other materials from the culture filtrate, or the fragmentation of polygalacturonase into active enzyme sub-units, are plausible explanations for the loss of large particles of enzyme. The apparent presence of negatively charged polygalacturonase particles in the enzyme component which should have been freed of negative enzyme by adsorption and elution from the cation exchanger may similarly be a result of dissociation of an enzyme complex during chromatography on the DEAE cellulose, as reported for other enzymes<sup>5</sup>.

Modifications of polygalacturonase may be influenced significantly by the method of regenerating the exchanger. For example, when DEAE cellulose was prepared for chromatography by Mandele's method<sup>6</sup> only a trace of polygalacturonase could be eluted from the column. The enzyme probably was inactivated during the exchange reactions, possibly by extreme dissociation.

Fig. 1. Fractionation of *Fusarium* polygalacturonase on a column of 'Sephadex G-200' with a void volume of 48 ml. □, Enzyme obtained from the culture filtrate; ●, chief components from a column of DEAE cellulose; ○, chief components from a column of 'Duolite CS-101'. Enzyme activity is expressed in units based on 100 for a 20 mm zone of enzyme activity in the cup plate assay.

The main polygalacturonase component from the culture filtrate adsorbed on 'Duolite CS-101' and eluted with 1.0 molar sodium acetate was dialysed and applied to a 'Sephadex G-200' column. Polygalacturonase was eluted continuously after the void volume with no peaks of activity corresponding to those obtained from the culture filtrate or the chief component from the DEAE cellulose column (Fig. 1). Failure to resolve polygalacturonase into distinct components could not have been due to saturation of the column because relatively small quantities of polygalacturonase were applied, but was probably caused by the recombination of polygalacturonase into complexes with particles of varying sizes. Recombination could be a result of association of enzyme molecules or sub-units to form a series of isoenzymes, or it could result from complexing of the enzyme with other molecules, for example, the pectic substrate that could have been carried along from the culture filtrate.

Knowledge of dissociation and recombination of polygalacturonase components will be helpful in the selection of methods for separation and purification of this enzyme and is a necessity for understanding the properties of polygalacturonases. Natural occurrence of polygalacturonase complexes may explain the heterogeneity of this enzyme from various microbial species, and account for the differences between polygalacturonase from diseased plants and culture filtrates of the pathogen<sup>1,7</sup>.

### Mechanism of Action of Carboxydismutase

THE mechanism of action of carboxydismutase—the enzyme which catalyses the fixing of carbon dioxide in plants—has been the subject of numerous investigations. The enzyme requires two substrates, ribulose-1,5-diphosphate (RuDP) and bicarbonate, and is found to form a <sup>14</sup>CO<sub>2</sub>-carboxydismutase complex<sup>1</sup>. If the isolated complex is stabilized with diazomethane and then digested with trypsin, the peptides formed can be isolated by ion exchange chromatography. It is found that only one of these peptides is highly radioactive, which suggests that the <sup>14</sup>CO<sub>2</sub> is bound to a specific site in the enzyme<sup>2</sup>.

The enzyme is inactivated by iodoacetamide (IAM) (ref. 3), but it can be protected by RuDP. This suggests a reaction between a sulphhydryl group and RuDP. It has also been concluded that the sulphhydryl group is the active site of the enzyme, and that one step of the overall enzyme reaction is the formation of a hemimercaptolate structure between the sulphhydryl group and RuDP (ref. 4). To determine the validity of this proposal we performed a number of experiments with other sugar phosphates as well as carbamyl phosphate (CBMP), sulphate and phosphate ions, and found that they too can protect the enzyme against inhibition by IAM, thus indicating that there are other interpretations for the findings.

Carboxydismutase was prepared from spinach chloroplasts (*Spinacea oleracea*) as described earlier<sup>5</sup>. The enzyme was incubated with IAM in the presence and absence of protectors. At different intervals aliquots were removed and the enzyme activity measured as before<sup>6</sup>.

IAM was found to inhibit the enzyme in a similar way to that reported by Rabin and Trown<sup>4</sup>. RuDP, fructose-1,6-diphosphate (FruDP), fructose-1-phosphate (Fru1P), fructose-6-phosphate (Fru6P), CBMP, or sulphate and phosphate ions at various concentrations suppressed the IAM inhibition (see Fig. 1). The protective power depends on the concentration of the suppressor and it is greater for CBMP. Fructose (Fru) protects the enzyme slightly at 4 mmoles but not at 1.5 mmoles/l. Glucose-6-phosphate (G-6-P) did not suppress the IAM inhibition at the concentration tested. The effect of sulphate and phosphate ions is quite pronounced, although higher concentrations are necessary. This finding, however, shows that the effect of a protector will be increased when sulphate or phosphate ions are present in the incubation mixture, and this was in fact observed with FruDP. After treatment with sodium sulphate, the calcium salt of FruDP was a much more potent protector than the salt itself. The RuDP used in our experiments was 40 per cent pure. In addition to sulphate ions, phosphate and ribose phosphate were present as impurities, and thus the effect of RuDP in protecting the enzyme from IAM inhibition was enhanced by the contaminants.

Initially, we thought that the effect of the sugar phosphates arose from their structural similarity to RuDP, and that the protection resulted from binding at the active site, thus making impossible alkylation by IAM. If this were so, however, it would be expected that FruDP would be a competitive inhibitor of the enzyme. Such an inhibition was not found up to a concentration of 4 mmoles/l. Even greater protection was provided by CBMP, which also does not inhibit the action of the enzyme up to the concentration tested (3 mmoles/l.). In addition, the enzyme is specific for RuDP (ref. 6). It is therefore difficult to visualize a mechanism in which IAM inhibits the enzyme by alkylating the active site, CBMP, FruDP and RuDP protect it by blocking the active site and do not allow the IAM to react, and yet FruDP or CBMP are not inhibitors or substrates of the enzyme. Moreover, if the protection of the sugar phosphates results from the formation of hemimercaptols with the sulphhydryl group, it would be expected that G-6-P would be a more potent protector than FruDP or RuDP, because aldehydes are more reactive to mercaptans than ketones<sup>7</sup>; however, this is not so. Finally, the pronounced effect of polyvalent ions would only justify an unspecific binding of the protector to the enzyme, and would bear no relationship to binding at the active site.

To obtain more information on the nature of protection of the enzyme by these compounds, the reaction leading to the formation of the  $^{14}\text{CO}_2$ -enzyme complex was studied<sup>1</sup>. Table 1 shows the results of a representative set of experiments. It is evident that IAM inhibits the formation of the  $^{14}\text{CO}_2$ -enzyme complex by about 50–60 per cent. As judged by the enzyme activity found and the  $^{14}\text{CO}_2$ -enzyme complex formed, FruDP protects the enzyme. Moreover, FruDP protects the enzyme from even the slow denaturation which probably occurs during the incubation period and the subsequent dialysis.

FruDP protects the enzyme against inhibition by IAM even for the formation of the  $^{14}\text{CO}_2$ -enzyme complex, and

Fig. 1. Time curve for the inhibition of carboxydismutase by IAM at 25°C in 0.1 molar *tris* buffer, pH 8.0, in the presence of different protectors. All reaction mixtures contained: enzyme, 0.9 mg/ml.; IAM, 0.5 mmoles/l.; protector (1) CBMP, 0.5 mmoles/l.; (2) Fru1P, 1.5 mmoles/l.; (3) Fru2P, 1.5 mmoles/l.; (4) RuDP, 0.5 mmoles/l.; (5) Fru1P, 1.0 mmoles/l.; (6) sodium sulphate, 15.0 mmoles/l.; (7) Fru2P, 1.5 mmoles/l.; (8) Fru2P, 1.0 mmoles/l.; (9) Fru1P, 0.5 mmoles/l.; (10) Fru2P, 1.0 mmoles/l.; (11) Fru2P, 0.5 mmoles/l.; (12) sodium monohydrogen phosphate, 15.0 mmoles/l.; (13) Fru 4.0 mmoles/l.; (14) Fru2P, 0.1 mmoles/l.; (15) G-6-P, 2.0 mmoles/l.; (16) control, no protector. Final volume 1 ml. The IAM was added at zero time to the reaction mixture containing the enzyme *tris* buffer and protector and the reaction was allowed to proceed at 25°C. 500  $\mu$ l. portions were removed at predetermined intervals and added at 0°C to tubes containing 50  $\mu$ l. of 0.01 molar cysteine in 0.2 molar *tris* buffer (pH 8.0). Magnesium (II),  $\text{H}^{14}\text{CO}_2$  and RuDP were then added and the reaction mixture was incubated at 25°C for 10 min. The RuDP, Fru1P and Fru2P were prepared from their barium salts<sup>1</sup>. The FruDP and CBMP were the calcium and lithium salts, respectively, and were not treated with sodium sulphate.

Table 1. EFFECT OF IODOACETAMIDE ON THE ACTIVITY OF CARBOXYDISMUTASE AND ON THE FORMATION OF THE  $^{14}\text{CO}_2$ -CARBOXYDISMUTASE COMPLEX, IN THE PRESENCE AND ABSENCE OF FRUCTOSE-1,6-DIPHOSPHATE

Sample	Enzymatic activity (c.p.m./mg protein)	Radioactivity of $^{14}\text{CO}_2$ -enzyme (c.p.m./mg protein)
Native enzyme	416,000	3,630
Native enzyme (No $\text{Mg}^{++}$ )		400
Enzyme + IAM	0	2,000
Enzyme + IAM + FruDP (5 mmoles/l.)	92,000	2,050
Enzyme + IAM + FruDP (10 mmoles/l.)	181,000	2,200
Enzyme + IAM + FruDP (20 mmoles/l.)	512,000	3,550
Enzyme + FruDP (10 mmoles/l.)	509,000	4,000
Native enzyme*	500,000	

Enzyme samples (5.3 mg/ml.) were incubated with IAM (5.0 mmoles/l.) at 25°C for 75 min in the presence or absence of FruDP. The same amount of enzyme but without IAM served as control. After the incubation the samples were dialysed against 0.02 molar *tris*, pH 8.0, at 2°C for 24 h, and then they were assayed for enzyme activity and were allowed to react with magnesium (II) and  $\text{H}^{14}\text{CO}_2$  at 0°C for 1 h to form the  $^{14}\text{CO}_2$ -enzyme complex<sup>1</sup>.

\* Not incubated and not dialysed.

therefore it seems that the protection is due to the formation of a hydrogen bond between the sugar phosphates or CBMP and the enzyme, so that its native form is preserved. The finding that 40 per cent of the  $^{14}\text{CO}_2$ -enzyme complex is still formed although the alkylated enzyme is inactive (Table 1) may also result from the structural alteration of the alkylated protein, the sites of attachment of " $\text{CO}_2$ " and RuDP being separated and thus no phosphoglycerate can be formed. This unfolding of the alkylated protein may also be responsible for the low recovery of the complex from the column, which renders the  $^{14}\text{CO}_2$  bound to the enzyme more easily exchangeable with the anion groups of the resin.

The existence cannot be disregarded of amino-acid residues responsible for the rigidity of the structure of the enzyme, for example, sulphhydryl groups, and which may be alkylated by IAM with a concomitant change in spatial configuration and inactivation. The protector may thus be bound on the same structure determining site (or sites), therefore making "attack" by IAM impossible and keeping the enzyme active. This site, however, cannot be considered to be "the" active site because that would be highly specific for the substrate.

Mention should be made of the effect of polyvalent anions and polyanions which can inhibit the spectral shift effect of 8 mmolar urea on ribonuclease<sup>8–10</sup>. Optical rotatory changes which occur during the denaturation of ovalbumin by urea are similarly influenced by anions<sup>11</sup>. Full activity in the presence of such denaturing agents results from refolding of the protein caused by the polyvalent anions. That the activity of carboxydismutase depends to a considerable extent on the folding over of the protein, which probably results in superimposition of the two active sites of the enzyme, is also evident from the activating effect of a magnetic field on the enzyme<sup>12</sup>; hydrogen bonding was considered to be the reason for the activating effect. The part played by sulphate and phosphate ions in preventing the inhibition of carboxydismutase by IAM may thus be understood.

## Chemical Form and Physiological Availability of Iodine in Lettuce (*Lactuca sativa*)

LITTLE information is available concerning the particular chemical form in which iodine occurs in plants<sup>1,2</sup>. It is known that the concentration of iodine in plant materials is directly related to that of the soil and may be affected by soil pH (ref. 1). Whether the iodine is organically bound in the plant, however, has not been properly established; furthermore, no physiological function has been found for this element in plants<sup>1,2</sup>.

The physiological availability of inorganic elements in plant materials has received a great deal of attention, and it has been shown that the availability of certain elements is related to the chemical form in which they are present. For example, there is evidence that phosphorus as inositol phosphate (phytic acid)<sup>3</sup> and iron as iron phytate are not well utilized<sup>4</sup>. The chemical form in which iodine is present in foods of plant origin may be of significance in areas of endemic goitre where vegetables represent the chief dietary source. It is conceivable that one of the contributing factors to the endemicity may be the physiological unavailability of plant iodine; that is, the iodine may be chemically bound in a non-utilizable form.

The present work was undertaken to investigate the chemical form in which radioactive iodine was incorporated into growing lettuce (*Lactuca sativa*, var. *longifolia*). In addition, the physiological availability of this iodine was studied in rats. Lettuce was chosen because of its rapid growth and because it is reputed to be a good source of iodine<sup>1</sup>.

Young, vigorous lettuce seedlings 8–10 cm high were transferred from soil into culture bottles containing a nutrient medium<sup>5</sup>. On the second or third day, radioactive iodine in the form of a solution of carrier-free Na<sup>125</sup>I was added to each container at the desired level of radioactivity. The plants were kept in a warm and well lit place for 7–25 days, depending on the type of experiment.

To investigate the uptake of radioiodine, plants were kept for 7 days in three different levels of radioactivity. At the end of the period, radioactivity was measured in leaf samples using a well type crystal scintillation counter; the results are shown in Table 1. It is evident that, at the levels of radioactivity used, uptake by the plants was in proportion to the amount of radioactivity present in the medium.

Table 1. UPTAKE OF IODINE-125 BY LETTUCE PLANTS GROWING IN VARIOUS LEVELS OF RADIOIODINE\*

Level of radioactivity in medium (μc.)	Radioactivity in plant (c.p.m./g fresh material)
16	650,000
32	1,100,000
64	2,430,000

\* Plants were kept in nutrient medium for 7 days.

The chemical form of the radioiodine in lettuce leaves was investigated in plant extracts using paper chromatography, column chromatography and paper electrophoresis. In addition, radioactive plant extracts were dialysed for the detection of possible non-dialysable forms of iodine. For the preparation of the extracts, plants were grown for 25 days in the culture medium in the presence of iodine-125 (20 μc./plant). The fresh leaves were then thoroughly washed with distilled water and homogenized with a minimum of distilled water. Clear extracts were collected as supernatant after centrifugation of the homogenates at 3,600 r.p.m. for 30 min; hereafter this material will be referred to as the "extract".

A portion of the extract was dialysed against distilled water for 3 days; the water was changed each day. At the same time a control solution of carrier free Na<sup>125</sup>I, containing the same level of radioactivity as the extract, was dialysed under the same conditions. In both the control and the extract, most of the radioactivity was found in the dialysate at the end of 3 days. The daily

portions of the plant dialysate were pooled and concentrated by flash evaporation to a volume of 10 ml. This concentrate, hereafter referred to as "dialysate", was used for further investigations.

**Paper chromatography.** The clear extract and dialysate were subjected to uni-directional chromatography on Whatman No. 1 paper with the solvent descending; a sufficient amount was applied so that the level of radioactivity at the origin was at least 5,000 c.p.m. In addition, a known concentration of Na<sup>125</sup>I was run alone on each chromatogram. Two solvent systems were used: (1) the top layer of a mixture of *n*-butanol, glacial acetic acid and water (4:1:5 v/v); (2) the top layer of a mixture of *n*-butanol, dioxane and normal ammonium hydroxide (4:1:5 v/v). Iodine is organically bound to certain proteins and amino-acids in the body of an animal, and therefore we endeavoured to determine radioactive areas on the chromatograms which were sensitive to ninhydrin. Each chromatogram was developed with a chloroform solution of 0.1 per cent ninhydrin and autoradiographs were prepared by exposing the chromatograms to X-ray film for 7 days. When the films had been developed, *R<sub>F</sub>* values were calculated for the blackened spots.

One radioactive spot appeared with both solvent systems on the chromatograms of extracts and dialysate. In butanol-acetic acid, the *R<sub>F</sub>* of the spot coincided not only with that of the standard iodine-125 but also with an area sensitive to ninhydrin (Table 2). In the dioxane-ammonia system, however, no ninhydrin spot developed at the peak of radioactivity (Table 2). The fact that, with one solvent, a radioactive area sensitive to ninhydrin was detected made necessary further work to establish the presence or absence of organically bound iodine.

Table 2. *R<sub>F</sub>* VALUES OF RADIOACTIVE PEAKS ON PAPER CHROMATOGRAMS OF LETTUCE PLANT EXTRACT AND DIALYSATE CHROMATOGRAPHED IN TWO DIFFERENT SOLVENT SYSTEMS

Material	Butanol-acetic acid	Dioxane-ammonia
Plant extract	0.187*	0.260
Dialysate	0.189*	0.264
Iodine-125	0.185	0.271

\* Coincided with an area sensitive to ninhydrin.

**Column chromatography.** For column chromatography, 200–400 mesh 'Dowex 50 WX8' resin (hydrogen form) was packed under water to a depth of 6 cm in a column 1 cm in diameter. This resin is known to bind organically bound iodine preferentially<sup>6</sup>. Similar amounts of radioactivity in the form of either plant extract, dialysate or Na<sup>125</sup>I were added to each of three columns; the columns were eluted with 2 ml. portions of deionized water. In all three instances negligible radioactivity appeared after the sixth fraction of eluent and the majority was eluted in fractions 2–5 (Fig. 1). The radioactivity in extract and dialysate left the columns more slowly than did the

Fig. 1. Peaks of radioactivity eluted from columns to which were added radioactive iodide (control), and dialysate and extract of lettuce grown in a medium containing Na<sup>125</sup>I. The resin used was 'Dowex 50WX8' (hydrogen form); the eluent was distilled water.

control, perhaps because in the former samples there was a certain amount of cellular material which may have hindered the movement of the iodine; however, the peaks for all three samples occurred consistently between fractions 2 and 6. It was found that, with all samples (even the control), about 10 per cent of the radioactivity remained on the resin and could not be removed by successive washings. These results strongly suggest that there was little or no organically bound iodine in the plant material.

**Paper electrophoresis.** Plant extract, concentrated dialysate and iodine-125 were electrophoresed on Whatman No. 3 paper at 300 V and pH 8.6. After electrophoresis, the papers were dried, sprayed with ninhydrin and autoradiographs were prepared. Initially, when the material was electrophoresed for 10 h, no radioactive spots were detected on the exposed film. By decreasing the time to 2 h, however, it was found that, as with the paper chromatograms, there was one peak of radioactivity in the extract and dialysate and that the peaks moved at the same rate as the iodine-125 standard. The relative positions of the three radioactive areas corresponding to iodine-125, lettuce extract and dialysate are shown in Fig. 2. All three radioactive spots moved similarly at a rapid rate toward the anode and were far out in front of the areas sensitive to ninhydrin. The results of the electrophoretic investigations indicated that all the iodine-125 taken up by the plant remained in the unbound inorganic form.

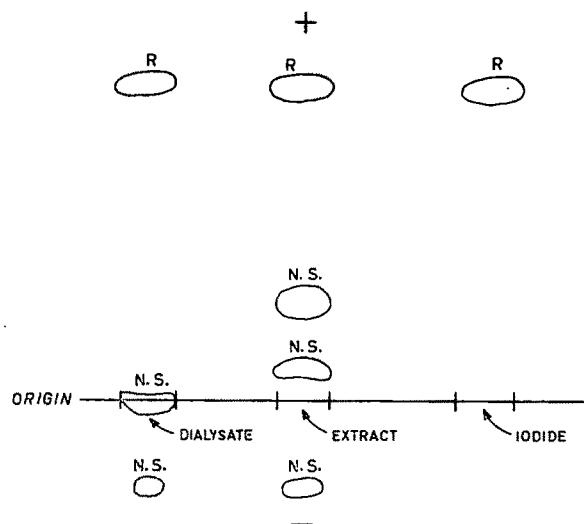

Fig. 2. Relative positions of radioactive (*R*) and ninhydrin-sensitive (*N.S.*) areas after paper electrophoresis of radioactive iodine and extract and dialysate of lettuce grown in a medium containing  $\text{Na}^{125}\text{I}$ . (2 h; pH, 8.6; 300 V.)

It was presumed that the radioiodine was in the water soluble fraction of the plant material. To investigate the possibility that some was present in the lipid fraction, however, a dried sample of radioactive plant material was continuously extracted with ether for 16 h. No radioactivity was recovered in the ether extract.

The following experiment was performed to see if the iodine as found in lettuce was physiologically available. Two growing male rats were rendered deficient in iodine by keeping them on a low iodine diet for 4 weeks. Each animal was then given, by gelatine capsule, about 5,000 c.p.m. of radioactivity in the form of dried powdered lettuce leaves. The animals were placed in metabolism cages so that urine and faeces could be collected separately; after 24 h, the rats were killed with chloroform and the thyroids removed. The results of radioactivity measurements in the urine, faeces and thyroids are shown in Table 3. These data suggest efficient utilization of the iodine because a large portion of the radioactivity was

Table 3. UPTAKE AND EXCRETION OF RADIOIODINE IN LETTUCE BY IODINE DEFICIENT RATS\*

Material	Radioactivity	
	Rat No. 1	Rat No. 2
Thyroid (c.p.m.)	2,330	1,870
Urine (c.p.m./ml.)	100	120
Faeces (c.p.m./g)	<100	<100

\* Each animal received 5,000 c.p.m. of radioactivity in the form of iodine-125 incorporated into lettuce; thyroids were removed 24 h after the animals received the radioiodine.

found in the thyroids while very little was detected in the urine and faeces.

In summary, it was concluded that, under the experimental conditions used, radioactive iodide was taken up readily by lettuce plants and appeared to remain in the plant in the unbound, inorganic form. Radioiodine incorporated into lettuce was readily absorbed and utilized in iodine deficient rats.

### Esterase and Phosphatase Activity in the Opisthosomal Region of Spiders

We have been able to demonstrate the presence of widespread intracellular and intercellular esteratic activity in the opisthosomal region of the dictynid species *Ciniflo fenestralis* (Stroem.) and the argiopid species *Zygiella atrica* (C. L. Koch). We used sections 5 $\mu$ –14 $\mu$  thick embedded in wax or frozen, and applied the 5-bromo-indoxyl acetate method<sup>1–3</sup>. The sections were fixed in acetone and incubated for 30–60 min in a medium containing 1.3 mg 5-bromo-indoxyl acetate dissolved in 0.1 ml. of ethanol. The alcoholic solution of 5-bromo-indoxyl acetate was used in a fresh solution containing 2.0 ml. of 0.1 molar 2-amino-2-hydroxymethyl-1,3-propanediol/hydrochloric acid buffer, 1.0 ml. of 0.05 molar potassium ferricyanide, 1.0 ml. of 0.05 molar potassium ferrocyanide, 1.0 ml. of 0.1 molar calcium chloride, and 5.0 ml. of water.

Generalized esterase activity was found in the cells of the interstitial tissue, the silk glands and in the haemolymph. This may be interpreted as demonstrating the widespread presence of esterases equivalent to the A, B and C esterases of vertebrates.

In contrast to this widespread distribution of generalized esterase activity the use of a modification of Gomori's calcium/cobalt method for alkaline phosphatase showed that phosphatase activity occurred predominantly at the periphery of the cells, especially the sericeogenous epithelia. The sections were incubated for 30–60 min at 37° C in a medium containing 10 ml. of 3 per cent sodium  $\beta$  glycerophosphate, 10 ml. of 2 per cent sodium diethyl barbiturate, 5 ml. of distilled water, 20 ml. of 2 per cent calcium chloride and 1 ml. of 5 per cent magnesium sulphate.

After rinsing in cold water they were treated with 2 per cent cobalt nitrate for 2 min and then, after rinsing, with a dilute solution of ammonium sulphide for 1 min.

Opisthosomal homogenates were subjected to electrophoresis on polyacrylamide gel columns for 45 min, and then incubated in the glycerophosphate solutions of Gomori's method. They showed a single moiety of low mobility with alkaline phosphatase activity. The moiety could be seen as a white disk after incubation. This rendered subsequent treatment with cobalt nitrate and ammonium sulphide unnecessary. Incubation of comparable gel columns using Barka's<sup>4</sup> method for acid phosphatase showed the presence of phosphatase activity at acid pH. It is worth noting, however, that in neither case did the inhibitors of vertebrate phosphatases, 0.01 molar sodium fluoride and 0.01 molar potassium cyanide, have any effect on these reactions.

Both acid and alkaline phosphatases have long been known to occur in insects<sup>5-8</sup>, and alkaline phosphatase is particularly common in epithelia secreting silk. It has been suggested that at this latter site the alkaline phosphatase may be involved in the release of silk from an intracellular nucleoprotein complex. It is clear that it may have a similar function in the silk glands of spiders.

### Topically Applied *n*-Decyl Acetate as a Precursor for Metabolic Investigations in Insects

WHEN small insects are injected with labelled metabolites trouble is caused by mechanical damage, excessive bleeding, clogging of the needle, and the serious distortion of metabolism which results from the sudden administration of up to 20 per cent of the insect's weight of water plus 10–60  $\mu$ moles of metabolite/g of live weight. One way to overcome these difficulties would be to make a fat-soluble acetate precursor which could be applied directly to the cuticle in the same way as an insecticide. The use of *n*-decyl 1-<sup>14</sup>C-acetate prepared by direct esterification of *n*-decyl alcohol has been investigated. No effect on mortality, pupation or emergence was found to result from topical application of acetone solutions, or even up to 1  $\mu$ l. of undiluted *n*-decyl acetate, to larvae of the blowfly *Calliphora erythrocephala*.

Each member of batches of eight blowfly larvae 3–4 days old was treated with 1  $\mu$ l. of undiluted and labelled *n*-decyl acetate, and the batches were placed in wire gauze cages. Each cage was suspended in a 15-ml. glass-stoppered tube containing 10 cm<sup>2</sup> of filter paper saturated with 10 normal potassium hydroxide. The experiment was conducted at 20° C. Every 30 min the cage was transferred quickly to a fresh tube and 3 h after treatment it was dropped into liquid nitrogen. The cage was then washed thoroughly in ethanol at –10° C and re-frozen. The larvae were extracted with perchloric acid<sup>1</sup>, and three times with chloroform and methanol (1 : 1) at room temperature, and the residue was heated for 24 h at 100° C in a sealed tube with 2 ml. of 50 per cent potassium hydroxide. The insoluble residue of chitin was washed with water and dried.

About one fifth of the activity recovered was metabolized and was found in carbon dioxide, fat-soluble, or water-soluble extracts. Small amounts of activity (less

Fig. 1. Production of carbon dioxide labelled with carbon-14 by insects. ○ — ○, Adult houseflies after injection with labelled acetate (ref. 2); ● — ●, larval blowflies after topical application of labelled *n*-decyl acetate.

than 0.1 per cent of the total recovered) were found in the alkaline digest of the residue and similar small amounts in chitin. Chromatography of fat-soluble extracts on thin layers of silicic acid with benzene and ether (60 : 40) as solvent failed to reveal any intact *n*-decyl acetate. This thin layer system was the only one out of many that were tested which separated *n*-decyl acetate from all the detectable insect fat fractions.

The production of labelled carbon dioxide at various times after topical application of the *n*-decyl acetate is compared with earlier data<sup>2</sup> from adult houseflies injected with labelled acetate (Fig. 1). There was no sign of a lag period between application of the ester and the evolution of <sup>14</sup>C carbon dioxide and it was concluded that *n*-decyl acetate is rapidly hydrolysed, and the free acetate produced further metabolized, as soon as it is absorbed by the insect.

These results demonstrate that the use of a fat-soluble precursor permits a water-soluble metabolite to be given to an insect, however small, in a dose smoothly applied over several hours without loss of blood, risk of mechanical damage or unnecessary metabolic disturbance.

I thank Mr. F. P. W. Winteringham, who first suggested that a fat-soluble acetate precursor might be a valuable tool.

### Absorption of Exogenous and Endogenous Biliary Copper in the Rat

THE daily intake of copper in man exceeds normal requirements<sup>1</sup>, but abnormally high body stores have only been recorded in Wilson's disease<sup>2,3</sup>. Knowledge of the exact mechanism of the absorption of dietary copper is incomplete<sup>4</sup> and even less is known about the absorption of endogenous biliary copper or its entero-hepatic circulation<sup>4,5</sup>. This report concerns the relative intestinal absorption of exogenous copper-64 in two chemical forms (ionic cupric acetate and chelated copper (II-EDTA)) and the absorption of endogenous biliary copper and caeruloplasmin copper.

Adult male Sprague-Dawley rats were given an intrapyloric dose of copper-64 either as cupric acetate or as copper (II-EDTA) in a dose range of 0.50–1,000  $\mu\text{g}$  of copper. The animals were killed after 24 h, the entire gastrointestinal tract was resected and the total radioactivity remaining in the carcass, liver and blood was used as the index of absorption.

For the absorption of biliary copper, bile was first obtained, through an external biliary fistula, from animals previously given an intravenous dose of 100  $\mu\text{g}$  of copper. Known amounts of copper in the biliary fractions taken at 0–4 h, 4–8 h and 8–24 h (both undialysed and dialysed) were then injected intrapylorically and absorption during 24 h was determined similarly. Finally, the absorption of 2.5  $\mu\text{g}$  of caeruloplasmin copper (prepared from donor rats) was measured.

The results are shown in Tables 1 and 2. A relatively constant fraction of the injected copper (about 40 per cent) was retained at 24 h when cupric acetate was given intrapylorically in the dose range of 0.50–10.0  $\mu\text{g}$ . With larger doses less was absorbed and with doses of 200 to 1,000  $\mu\text{g}$  of copper only 10 per cent was retained. Similar results were obtained with labelled copper (II-EDTA).

When biliary copper was given intrapylorically in doses of 0.50 to 10.0  $\mu\text{g}$ , 10 per cent to 15 per cent was absorbed by 24 h. At a constant dose of 2.5  $\mu\text{g}$  of endogenous undialysed bile copper, absorption decreased progressively when the fractions of bile taken at later times were injected (15 per cent absorption for the 0–4 h fraction and 9 per cent absorption for the 8–24 h fraction). This occurred when the dialysed bile was used. After an intrapyloric dose of 2.5  $\mu\text{g}$  of caeruloplasmin copper approximately 10 per cent of the label was retained.

Table 1. PERCENTAGE ABSORPTION OF COPPER ACETATE AFTER 24 H

Dose ( $\mu\text{g}$ )	No. of experiments	Percentage absorption (mean $\pm$ S.D.)
Cupric acetate		
0.5–10.0	19	38.2 $\pm$ 13.6
50.0	3	19.8 $\pm$ 7.2
200	3	8.7 $\pm$ 1.8
500	3	10.17 $\pm$ 4.0
1,000	2	11.5
Copper (II-EDTA)		
2.5	3	27.9 $\pm$ 3.1
200	2	16.73

Table 2. PERCENTAGE ABSORPTION OF BILIARY COPPER AT 24 H

Dose ( $\mu\text{g}$ )	Bile fraction	No. of experiments	Percentage absorption (mean $\pm$ S.D.)
Cupric acetate			
2.5–10.0	0–4 h	5	16.7 $\pm$ 3.9
0.5–5.0	4–8 h	6	16.20 $\pm$ 5.5
2.5	0–4 h*	5	15.63 $\pm$ 2.8
2.5	4–8 h*	6	12.30 $\pm$ 4.8
2.5	8–24 h*	3	9.64 $\pm$ 2.9
Copper (II-EDTA)			
2.5	0–4 h	3	21.6 $\pm$ 4.2
2.5	4–8 h	2	12.73
2.5	8–24 h	2	7.59

\* Dialysed fractions.

With increasing amounts of exogenous copper, there is a progressive reduction in the absorption of biliary copper irrespective of which of the two chemical forms was used. Endogenous biliary copper is poorly absorbed even with small doses, which contrasts with the relatively greater absorption of exogenous copper (Fig. 1). This difference is probably due to the indiffusibility and protein binding of biliary copper<sup>3</sup>. The differing degree of absorption in the three bile fractions (0–4, 4–8, 8–24 h) when identical amounts (2.5  $\mu\text{g}$ ) of bile copper is used, when the bile had been dialysed in each case, suggests a change in the copper protein complex with increasing time after intravenous administration.

The results of these investigations in the rat might explain the zero copper balance in man despite a relatively high intake of dietary copper. The excessive exogenous copper is poorly absorbed, but experiments in the rat show this to be quantitatively significant. The subsequent biliary excretion<sup>4</sup> and poor reabsorption of biliary copper,

Fig. 1. Percentage absorption of 2.5  $\mu\text{g}$  of labelled copper acetate, showing stock and dialysed bile copper.

that is, lack of significant entero-hepatic circulation, may represent the chief pathway for the elimination of copper from the body.

### Chromatography of Gibberellins on Silica Gel Partition Columns

ALTHOUGH there are many chromatographic methods for separating the various gibberellins from each other, there appears to be no report of the use of silica gel partition columns. Columns are more useful for preparative separations than thin layer and paper chromatographic methods. Methods using absorption columns made with charcoal and silicic acid have been described<sup>1,2</sup>. Partition columns are usually considered to provide especially mild conditions for chromatography, which may be important with compounds that tend to be somewhat labile, such as the gibberellins.

We have used two silica gel partition column techniques. The first technique, which employs gradient elution, uses a column constructed from silicic acid which has been washed with 3 N hydrochloric acid, then water, and finally dried to constant weight at 100° C. Eight grams of a 100–200-mesh fraction of this silicic acid (silica gel)

was hydrated with 5.0 ml. of 0.5 molar formic acid and thoroughly mixed until a free-flowing powder was obtained. The hydrated silica gel was then slurried with *n*-hexane that had been saturated with 0.5 molar formic acid, and poured into a 15-mm internal diameter glass column with a stopcock on one end. The column was packed with air pressure from a hand squeeze bulb while excess hexane was drained from the column. Residues containing gibberellins may be applied to the top of the column by various means<sup>3,4</sup>, but the technique used here consisted of first transferring the gibberellins dissolved in alcohol to a small paraffin boat (capacity about 5 ml.), evaporating the alcohol, then applying the paraffin boat with residue to a few millilitres of acid-saturated *n*-hexane contained on top of the column. After the paraffin had dissolved it was washed through the column with about 30 ml. of *n*-hexane, leaving behind on the column the gibberellins and most other plant constituents. The gibberellins were eluted from the column by using increasing concentrations of ethyl acetate in *n*-hexane. The solvent gradient was established with a 3-chambered 'Varigrad' similar to the device described by Peterson and Sober<sup>5</sup>. The first chamber of the 'Varigrad' was filled with 100 ml. of *n*-hexane saturated with 0.5 molar formic acid, while the other two chambers each contained 75 ml. of ethyl acetate saturated with 0.5 molar formic acid. After elution of the column, the 10-ml. fractions were dried in a device especially designed for rapid evaporation of solvents from test-tubes at low temperatures. The residues were analysed for gibberellins either by thin layer chromatography<sup>6</sup> or by the lettuce hypocotyl bioassay<sup>7</sup>. More detailed description of the use of these columns may be found in earlier papers describing their use for the chromatography of indoles<sup>3,4,8</sup>.

Table 1. GRADIENT ELUTION PATTERNS FOR GIBBERELLINS  $A_{1-5}$  FROM SILICA GEL PARTITION COLUMNS

Fraction No.	Gibberellins eluted
1-4	$A_4, A_3, A_2, A_1, A_5$
11-15	$A_4, A_3, A_2$
18	$A_4$

The results are shown in Table 1. The least polar gibberellins ( $A_4$  with no hydroxyl groups, and  $A_4, A_3, A_2$  and  $A_1$ , each with one) were eluted in the first four fractions. Gibberellins  $A_1, A_2, A_3$ , each with two hydroxyl groups, emerged in fractions 11 to 15.  $GA_4$ , with three hydroxyl groups, was found in fraction 18. This technique, therefore, separates gibberellins  $A_{1-5}$  into certain groups with similar polarity, but, perhaps more important, it can be used to separate many of the other plant constituents from the gibberellins. Polar substances such as many of the common organic acids, sugars, amino acids and some pigments are not eluted. A number of non-polar substances, however, such as the lipids and some of the indoles, are eluted in the same general region as the gibberellins. The lipids may be separated from the gibberellins by partitioning between acetonitrile and hexane, the gibberellins being dissolved into the acetonitrile.

The other silica gel column technique employed stepwise elution of the gibberellins from a column identical with that described for the gradient elution technique. When the column was eluted with 25-ml. volumes of a series of solvents with increasing concentrations of ethyl acetate in *n*-hexane (all solvents were saturated with 0.5 molar formic acid) most of the gibberellins ( $A_{1-5}$ ) were separated from each other. As with the first method, many of the chief plant constituents are left behind on the column. The eluting solvents used, and the elution pattern for the gibberellins, are summarized in Table 2. This method does not give complete separation of  $GA_4$  and  $GA_1$ , nor of  $GA_1$  and  $GA_2$ , but the results suggest that some improvement might be obtained by either modifying the percentage of ethyl acetate in the fractions where better resolution is desired, or by increasing the length of the column.

These two techniques have proved useful in our gibberellin investigations of plant tissues. The first is a rapid one (2-3 h) for obtaining considerable purification of the gibberellins, and gives the investigator some idea of the types of gibberellins with which he may be dealing. The second method, though more time consuming (5-6 h), permits better characterization of the gibberellins. Four recovery experiments with  $GA_4$  gave more than 90 per cent recovery in each case<sup>9</sup>. The quantities of gibberellins used in this work ranged from a fraction of a microgram to 10 micrograms. We have not had the opportunity of comparing our methods with the gradient elution silica gel adsorption column technique for gibberellins recently announced by Khalifah *et al.*<sup>2</sup>, with which they were able to separate seven acidic gibberellins with good recovery.

The authors are indebted to Prof. P. W. Brian for supplying the gibberellins used in this work.

## MICROBIOLOGY

### Effect on the Infectivity of Various Viruses by the Intestinal Factor of Normal Mice which inactivates Murine Hepatitis Virus

THE capability of the intestine of normal mice to inactivate murine hepatitis virus (MHV-3) (ref. 1) has been reported<sup>2</sup>. The inactivating factor is present mainly in the first section of the mucosa of the small intestine of the adult mouse<sup>3</sup>; it is present in the intestine of germ-free mice<sup>4</sup>, and its interaction with the virus *in vitro* is dependent on temperature and incubation time<sup>5</sup>. The factor is inactivated at 70° C for 10 min, is not dialysable and is not present

in acetone-dried powders of mouse intestine<sup>5</sup>. The present paper deals with the effect of the partially purified inhibiting factor on the infectivity of several viruses.

The inhibiting factor was prepared in the following manner. Small intestine of normal mice 3 months old and weighing about 30 g was excised from the animals, washed to remove any faecal debris, and mechanically homogenized in three volumes of buffered saline. The suspension was then centrifuged at 30,000*g* for 60 min at 4° C and the sediment was discarded. The supernatant was saturated with ammonium sulphate and the precipitate was collected by centrifugation and dissolved in a minimum volume of distilled water. The resulting solution was dialysed against a 40 per cent saturated ammonium sulphate solution, and the precipitate formed was discarded by centrifugation. The supernatant was then dialysed against a 70 per cent saturated ammonium sulphate solution. The precipitate was again collected by centrifugation, dissolved in a minimum volume of 0.05 molar *tris*-hydrochloric acid buffer pH 7.4, and thoroughly dialysed against the same buffer; this preparation was used in all the experiments.

Titration of the partially purified inhibiting factor was carried out as follows. Progressive dilutions of the inhibitor in a volume of 2.0 ml. were incubated for 2 h at 37° C in a water bath with an equal volume of a suspension of *MHV*-3 containing 10<sup>6</sup> LD<sub>50</sub>/0.1 ml. Groups of ten 4 week old Swiss mice, weighing 12 g each, were injected intraperitoneally (0.2 ml./mouse) with each sample and mortality was recorded. The value of 1 unit was assigned to the amount of inhibitor contained in the highest dilution which neutralized 10<sup>6</sup> LD<sub>50</sub> of *MHV*-3.

Table 1. EFFECT OF PARTIALLY PURIFIED MOUSE INTESTINAL FACTOR ON THE INFECTIVITY OF VARIOUS VIRUSES

Virus	Strain	Inhibitor units	Log <sub>10</sub> LD <sub>50</sub> neutralized	Host-cell system
Murine hepatitis virus	<i>MHV</i> -3	1	0.00*	Mouse
Influenza A	PR 8	1	1.23	EE
Influenza A	PR 8	5	2.75	EE
Influenza A	FM 1	1	1.16	EE
Influenza A	Singapore	1	1.83	EE
Influenza B	Lee	1	1.20	EE
Influenza B	Lee	5	2.50	EE
Newcastle disease virus	B 1	1	0.00	EE
Newcastle disease virus	Local	1	0.00	EE
Infect. bronch. chicken	Beaudette	1	1.50	EE
Measles	Edmonston	1	0.83	HeLa
Rubella	M 33	1	≥3.50†	GMKC
Poliomyelitis:				
Type 1	Brunhilde	5	0.00	GMKC
Type 2	MEF-1	5	0.00	GMKC
Type 3	Saukett	5	0.00	GMKC
ECHO-11		1	0.00	GMKC
ECHO-11		5	0.66	GMKC
Coxsackie A-9		1	2.00	GMKC
Coxsackie B-5		1	0.00	GMKC
Encephalomyocarditis	EMC	5	0.00*	Mouse
Simian virus 40		1	1.16	GMKC
Variola	Lister	1	1.00	HeLa

\* LD<sub>50</sub>; † interfering dose<sub>50</sub>.

EE = Embryonated eggs; GMKC = green monkey kidney cells.

Each mouse was injected intraperitoneally with 0.2 ml. of the different mixtures. Each tissue culture tube or egg (allantoic route) received 0.2 ml. of the mixture. For each virus the experiment reported in Table 1 is one of three which gave similar results.

In order to compare the activity of the inhibiting factor on the infectivity of various viruses the following procedure was used. Serial ten-fold dilutions of each virus preparation were made up in buffered saline solution; each virus dilution was dispensed into two series of tubes containing (a) an equal volume of buffered saline, or (b) an equal volume of inhibitor in the proper concentration, respectively. The two series were incubated at 37° C for 2 h and frequently shaken. The inhibiting effect was evaluated by inoculating the mixtures into susceptible host-cell systems, and by determining the LD<sub>50</sub> according to the method of Reed and Muench<sup>6</sup>.

From the data which are summarized in Table 1, a weak inhibitory effect is apparent on the infectivity of influenza, measles, infectious bronchitis of chicken, coxsackie A-9, *SV*-40 and variola viruses. With the exception of rubella virus, the inhibitory effect seems to be highly specific for *MHV*-3, at least for the viruses tested. No effect on the haemagglutinating activity of influenza and measles viruses was observed when 1 unit of inhibitor was tested against 4 haemagglutinating units of the respective viruses.

### Facilitated Uptake of Streptomycin by Kupffer Cells during Phagocytosis

PHAGOCYTOSIS and intracellular digestion of bacteria have been investigated primarily with blood leucocyte or peritoneal macrophages derived from experimental animals. Many attempts have been made to isolate the intracellular events by the addition of bactericidal concentrations of streptomycin to the extracellular medium after the phagocytic cells have ingested the bacterial particles. The assumption made is that streptomycin by virtue of its relative impermeability exerts no bactericidal or bacteriostatic effect on those bacteria which are established intracellularly. Data concerning penetration of streptomycin into mammalian cells, however, are not consistent and seem to depend on the types of cell and the methods of assay for streptomycin which are used. The general conclusion is that the antibiotic is not concentrated intracellularly in quantities large enough to be bactericidal<sup>1-3</sup>. A critical examination of the data, however, shows that such a conclusion may not be entirely warranted in all cases<sup>4-7</sup>, and consequently the extent of bactericidal activity which streptomycin exhibits for intracellular bacteria remains conjectural.

During an investigation to measure the kinetics of phagocytosis of viable bacteria by the isolated, perfused rat liver<sup>8</sup>, the presence of streptomycin in the perfusing fluid caused an apparent increase in inactivation of phagocytosed organisms; that is, greater than that which could be accounted for by phagocytic digestion alone. This observation suggested several alternative mechanisms which could account for the decreased recovery of viable bacteria. (1) The fixed macrophages of the liver may possess properties of permeability to streptomycin different from those of the blood leucocytes and mobilized macrophages. (2) A significant number of bacteria were adsorbed to the surfaces of capillaries and Kupffer cells and these could not be washed out mechanically before the addition of streptomycin. (3) The process of phagocytosis itself facilitated the uptake of streptomycin in a fashion analogous to the 'piggy back' phagocytosis phenomenon<sup>9</sup>, described when anti-metabolites which were ordinarily impermeable accumulated intracellularly if the cells were allowed to phagocytose latex particles in a medium containing the impermeable compounds.

This communication describes an experiment which was designed to distinguish between these possibilities and which provides tentative evidence supporting a hypothesis. Rat livers were surgically removed and perfused with serum as described previously<sup>2</sup>. Three sets of experimental conditions were imposed during the first 30 min of perfusion; (a) livers were perfused with normal serum containing killed *Salmonella enteritidis* in a concentration of  $1 \times 10^8$ /ml.; (b) livers were perfused with normal serum containing 1 mg/ml. of streptomycin sulphate (this concentration of antibiotic was far greater than the minimal inhibitory concentration); (c) livers were perfused with normal serum containing the non-viable salmonellae plus 1 mg/ml. of streptomycin sulphate. After the 30 min period, the three groups described were treated identically for the duration of the perfusions. The livers were washed thoroughly with warm sterile physiological saline to remove any extracellular non-viable salmonellae and (or) reduce the concentration of streptomycin to a non-bactericidal level of 0.5 µg/ml. The circulation through the livers was then re-established with normal serum containing viable *Salmonella enteritidis* in a concentration of  $1 \times 10^8$ /ml. After 2 h of perfusion warm saline was again allowed to flush out any non-phagocytosed organisms. The number of viable bacteria within the Kupffer cells was then determined by plating methods immediately after the perfusion.

The data (Table 1) suggest that streptomycin does not penetrate the Kupffer cells of the liver in quantities sufficient to exert a bactericidal effect on organisms later phagocytosed. On the other hand, the recovery of only 40 per cent of the viable salmonellae phagocytosed during 2 h of the secondary perfusion in the group which had been perfused initially with killed bacteria and streptomycin<sup>3</sup> provides evidence that the presence of particles in the perfusing menstrium allowed the intracellular accumulation of the antibiotic.

Table 1. RECOVERY OF VIABLE PHAGOCYTOSED *Salmonella enteritidis* FROM PERFUSED RAT LIVERS FOLLOWING PRETREATMENT WITH STREPTOMYCIN AND/OR NON-VIABLE SALMONELLAE

Primary perfusion (30 min)	Constituents in perfusate Secondary perfusion (120 min)	Percentage recovery of viable bacteria*
Group I (controls)		
Non-viable <i>S. enteritidis</i> ( $1 \times 10^8$ /ml.)	Viable <i>S. enteritidis</i> ( $1 \times 10^8$ /ml.)	131
Group II		
Streptomycin (1 mg/ml.)	Viable <i>S. enteritidis</i> ( $1 \times 10^8$ /ml.)	121
Group III		
Non-viable <i>S. enteritidis</i> ( $1 \times 10^8$ ml.) and streptomycin (1 mg/ml.)	Viable <i>S. enteritidis</i> ( $1 \times 10^8$ /ml.)	40

The probability that differences observed between group III and groups I and II are a result of chance is less than 1 in 1,000 ( $P < 0.001$ ). Differences between groups I and II are not statistically significant.

\* Percentages were calculated on the basis of results of three separate experiments for group I, two experiments for group II, and four experiments for group III.

Several speculations can be made as to the mechanism by which this phenomenon can be explained. The most plausible is that the streptomycin sulphate which is usually impermeable to the phagocytic cell gains entrance by a process similar to the "piggy back" process already described. An alternative mechanism is that the antibiotic is bound to receptor sites on the outside surface of non-viable bacteria and is then carried in with the bacteria as they are phagocytosed. It must in this case be assumed that the bound streptomycin is still functional and free to act on other bacteria once inside the Kupffer cells. The possibility that the decreased recovery of salmonellae may be a result of the killing of organisms which are not phagocytosed but adsorbed instead to surfaces of cells and capillaries cannot be ignored. No matter how thoroughly the livers were rinsed, we invariably obtained small numbers of viable bacteria in the wash fluids. Histological examination of sections prepared at the termination of

each experiment, however, showed that the bacteria were located intracellularly. Bacteria were detected outside phagocytic cells only in rare instances.

The results of this experiment cannot be considered definitive, but clinical evidence provides the most compelling argument that streptomycin can be concentrated within phagocytic cells by some mechanism. If this were not the case it would be difficult to explain the efficacy of the antibiotic in the treatment of intracellular infections such as tuberculosis, brucellosis and tularaemia.

### Mycostasis in Soils recently Exposed by a Retreating Ice-cap

SOIL mycostasis is a familiar and widespread phenomenon which has recently been reviewed in some detail<sup>1,2</sup>. Its nature and mode of action are obscure, but it is considered to be of microbial origin and has been found to be pronounced where microbial activity is high and less where microbial activity is low. Studies have usually been made on agricultural soils or those which at some time have supported vegetation and, apart from a study of some subsoils, investigations of "virgin" soils with few traces of plant residues have not often been made.

In an attempt to obtain information on the appearance of mycostatic effects in natural soils, a study was made of soil polygons from near the western edge of the Drangajökull in north-west Iceland. Extensive polygon fields occur here in an area which has been exposed by the retreating ice during the past 50 yr.

Where soil movement is not pronounced, the polygon margins are colonized by higher plants providing there is some shelter from the desiccating winds blowing from the ice-cap and good drainage of surface water. The polygon centres are free of vegetation, as marked solifluction, exposure to desiccating winds, and periodic waterlogging preclude the establishment of seedlings<sup>3</sup>.

Soil samples of about 500 g each were taken from polygons at 400, 800 and 1,000 m from the present ice limit. At each site three samples from different polygon centres were taken and three separate samples from around the roots of the three common colonizers of the margins: *Armeria maritima* (Mill.) Willd., *Deschampsia alpina* (L.) Roem. and Schult., and *Oxyria digyna* (L.) Hill. Samples were collected in August 1965 and mycostasis assessed in the laboratory in November of the same year. The method used was the agar disk technique<sup>4</sup> with week-old conidia of *Penicillium frequentans* Westling as test spores. Soils were first passed through a 1 mm mesh sieve and their moisture content adjusted with distilled water to almost 100 per cent of their total water holding capacity. Spore germination was scored after 24 h incubation at 25° C.

The numbers of fungi present in each sample were estimated using the dilution plate method<sup>5</sup>, and organic matter determined by loss on ignition. Average results are shown in Table 1.

Both the content of organic matter and fungal numbers were consistently higher at the margins than in the centres of the polygons. At the uncolonized centres mycostasis was invariably high, yet here the soil contained little organic material and its fungal population, and probably the population of other soil micro-organisms, was relatively small. The fungi and other components of the microflora were presumably mainly present as propagules and not actively growing in the soil.

Table 1. AVERAGE PERCENTAGE GERMINATION OF *P. frequentans* CONIDIA, FUNGAL POPULATION AND LOSS ON IGNITION FOR POLYGON SOILS

	Distance from ice (m)					
	400		800		1,000	
	Margin	Centre	Margin	Centre	Margin	Centre
Fungal/g of oven-dry soil, in thousands	291	45	74	72	115	18
Per cent germination conidia	12.6	0	32.0	0	11.3	3.6
Per cent loss on ignition	4.3	2.6	4.2	4.1	5.4	3.1

Average values from each sample site are from three non-colonized (centre) and three colonized (margin) soils.

Where the three colonizers were present there was an alleviation of mycostasis at the margins although the level of this was not consistently the same at each sampling site. At the margins there was a higher level of organic matter as a result of the return of root and foliage material to the soil and microbial numbers were relatively high and presumably reflected a higher level of activity, yet as much as 87 per cent germination was recorded on disks in contact with soil from around the roots of *D. alpina*.

In natural soils amelioration of mycostasis is observed when nutrients are added to them<sup>6</sup>. Mycostasis is regarded as having survival value for soil fungi since sensitive spores will lie dormant until stimulated by contact with soluble nutrients so that spore wastage caused by random germination is reduced or eliminated. The effect is not generally considered to be a result of nutrient deficiency in either the spore or the soil but more of the presence of an inhibitor or group of inhibitors produced as a result of microbial activity. It has been pointed out, however, that lack of nutrient is still a possible basis for some mycostatic effects because conditions for germination in soil might be much more exacting than those under artificial conditions<sup>7</sup>.

It appears that such a situation exists at the place described where, during the early stages of the colonization of a natural "virgin" soil by both higher plants and micro-organisms, mycostasis does occur as a result of factors other than those which arise as a consequence of microbial activity. Mycostasis at polygon centres might be caused by a nutrient lack while at the margins nutrients are more abundant but microbial activity is not so high as to produce a mycostatic effect through the release of metabolites to the soil. It is suggested that a more extensive study of the appearance of mycostasis in freshly exposed soils might lead to a better understanding of the basis of the phenomenon.

## PHARMACOLOGY

### Effect of Tetrodotoxin on Membrane Currents in Mammalian Cardiac Fibres

THE action potential of cardiac fibres differs from that of most other cell types: the fast rising phase is followed by a plateau lasting a few 100 msec. The results of voltage clamp analysis in Purkinje fibres<sup>1</sup> show that a depolarizing voltage step elicits a large sodium current, which has a slow component which declines for several hundred milliseconds. The potassium current falls after depolarization with a similar time constant. The slow decline of both currents can explain the plateau of the cardiac action potential. The sodium current was identified by comparing the membrane currents in Tyrode solution with those in a sodium-free solution<sup>2</sup>. An independent check of this procedure would be useful; we therefore investigated the effect of tetrodotoxin (TTX) on short Purkinje fibres of sheep. TTX at concentrations of  $10^{-8}$  to  $10^{-7}$  g/ml. is known to block selectively the excitatory inward sodium current in invertebrate axons<sup>2,3</sup>. We recorded membrane potentials in fourteen preparations and passed current through a second intracellular glass microelectrode. Details of the preparation and of the electronic apparatus are given elsewhere<sup>4</sup>.

In a concentration of  $10^{-8}$  to  $10^{-6}$  g/ml. TTX surprisingly had no effects on the rate of rise and duration of the action potential of the Purkinje fibre. Specific effects of TTX were observed in the range of concentrations from  $10^{-5}$  to  $3 \times 10^{-5}$  g/ml. At  $10^{-4}$  g/ml. TTX, the preparation was depolarized to about  $-20$  mV. The effective concentrations of TTX are peculiarly high compared with those required in other tissues<sup>2,3</sup>.

TTX in a concentration of  $10^{-5}$  g/ml. often led to a progressive slight depolarization, and the rate of rise of the action potential was always slowed and its plateau phase simultaneously shortened. In Fig. 1 (dashed curves) the action of the drug after 7 min has reached a steady state. The "action potential" in the presence of TTX has an ill defined high threshold. The rate of rise in Fig. 1B is reduced to one-tenth, and the regenerative component of the potential rise is small. The low rate of rise under the action of TTX cannot be explained by the depolarization of the resting potential from  $-102$  to  $-89$  mV<sup>5</sup>. The repolarization phase in TTX is fast, but not altogether passive. It is remarkable that the pacemaker potential at the end of the action potential is not affected by TTX. All the effects of TTX on the action potential, including the rate of rise, are reversible within 10 min of washing. More quantitative information on the action of TTX can be obtained through voltage clamps. In Fig. 2 the membrane was depolarized in four rectangular steps starting from a holding potential of  $-104$  mV. The same steps were repeated in  $10^{-5}$  g/ml. TTX. Since the resting membrane is depolarized in TTX (Fig. 1), increased negative currents were necessary at the holding potential. In the controls of Fig. 2 B-D, a negative current appears at the beginning of the depolarization which rapidly subsides. This is the equivalent of the excitatory sodium current. In TTX the record of the current assumes a nearly rectangular shape, and most of the sodium current seems to be blocked. The current amplitude at the end of the depolarization step is, however, little affected by TTX. The declining current following repolarization of the voltage change is also uninfluenced by TTX, except that the threshold at which this current component appears is shifted under TTX from 20 mV depolarization (Fig. 2A) to 40 mV depolarization (Fig. 2B). This current flowing after repolarization is the equivalent of the pacemaker potential.

If TTX blocks the sodium current, one would expect essentially the same membrane currents in the presence of TTX as in the absence of sodium. This is, however, not the case. In a sodium-free solution at the beginning

Fig. 1. *A*, Intracellularly recorded action potential; *B*, rate of change of this potential. Continuous curves represent controls in Tyrode solution, dashed curves measured in presence of  $10^{-5}$  g/ml. tetrodotoxin. The horizontal arrow in *A* denotes the peak of the dashed action potential. The stimulating current pulse was 20 msec long, its amplitude (threshold) was  $3 \times 10^{-7}$  amp in the control, and  $5 \times 10^{-7}$  amp in TTX. Ordinates in *A* and *B* represent membrane potential; abscissa in *A* represents time, in *B* rate of change of potential. The latter value was measured without distortion using an operational amplifier. Note the change in calibration in *B*.

of the depolarization step the positive current is much larger than in TTX, but falls, within a few 100 msec, to the same steady level as in TTX (compare ref. 1, Fig. 1; and ref. 6, Fig. 2). The clamp current in sodium-free solution is not affected by TTX. It seems that one of two possible conclusions can be drawn: (a) TTX does not completely block the excitatory sodium current, and has relatively little influence on a slowly declining component. (b) The

falling positive current component is only generated in sodium-free solution and is not contained in the current measured in Tyrode solution. We think that several lines of evidence tend to favour the first alternative. Experiments to clarify this issue are in progress.

All our results on the action of TTX can be explained if, on an analogy with other excitable cells, this drug inhibits inflow of sodium during depolarization. Thus our experiments are further evidence for the assumption that the fast inflow of sodium ions initiates the cardiac action potential<sup>5</sup>. The results may suggest some independence of an early, rapidly declining, and a later, slowly falling, component of the sodium inward current. The later component of the sodium current may be less sensitive to TTX than the early one. Hagiwara and Nakajima<sup>6</sup> have reported effects of TTX on frog ventricular fibres which are similar to our results shown in Fig. 1. They found that the rate of rise of the action potential slowed, whereas the plateau phase was less affected. The authors concluded that considerable inward flow of calcium maintains the plateau phase of the cardiac action potential, and this calcium current is insensitive to TTX. We do not think that these results should necessarily be explained by a calcium current. An alternative explanation is a slow component of the sodium current less influenced by TTX. In Purkinje fibres the relative insensitivity of slow negative current components towards TTX cannot be due to a calcium current. In this tissue it has been shown that no appreciable calcium current flows during the plateau phase of the action potential<sup>7</sup>. We do not believe, therefore, that inward currents insensitive to TTX are necessarily calcium currents.

### Inhibition of the Extraneuronal Metabolism of Noradrenaline in the Isolated Heart by Adrenergic Blocking Agents

ADRENERGIC blocking agents inhibit the response of effector cells to noradrenaline and related amines<sup>1</sup>; several of these drugs also act as inhibitors of the uptake of noradrenaline into sympathetic nerves<sup>2,3</sup>. This communication describes a novel action of adrenergic blocking agents, the ability to inhibit the extraneuronal metabolism of noradrenaline in a peripheral tissue.

Hearts from adult male Sprague-Dawley rats were perfused by the Langendorff technique for 10 min with Krebs-Henseleit bicarbonate solution at 37° C (ref. 4). Tritiated noradrenaline, cocaine and adrenergic blocking agents were added to the perfusion medium. Cocaine was used to reduce the uptake of noradrenaline by sympathetic nerves. At the end of the perfusion the tissue was analysed for tritiated noradrenaline and its metabolites by methods previously described<sup>5,6</sup>. In other experiments the effects of adrenergic blocking agents on the *in vitro* activity of the enzymes catechol-O-methyl transferase<sup>7</sup> and monoamine oxidase<sup>8</sup> were studied in heart homogenates.

Table 1. EFFECT OF ADRENERGIC BLOCKING AGENTS ON THE EXTRANEURONAL METABOLISM OF NORADRENALINE IN THE ISOLATED PERFUSED RAT HEART

Drugs administered	Normetanephrine	Deaminated* catechols	O-methylated† deaminated	Noradrenaline
NA	180 ± 31	25 ± 2.5	**	3,000 ± 310
NA C	280 ± 18 ‡	15 ± 1.7 ‡	56 ± 5.6	240 ± 46 §
NA C Phentolamine 10 <sup>-4</sup> molar	20 ± 2.3 ¶	3.2 ± 0.46 ¶	14 ± 1.8 ¶	45 ± 7.4
NA C Phenoxybenzamine 10 <sup>-4</sup> molar	10 ± 3.3 ¶	1.4 ± 0.31 ¶	14 ± 3.1	29 ± 3.2
NA C Dichloroisoprenaline 10 <sup>-4</sup> molar	110 ± 14 ¶	4.1 ± 0.40 ¶	27 ± 6.0	79 ± 3.9
NA C Pronethalol 10 <sup>-4</sup> molar	124 ± 10 ¶	5.3 ± 0.63 ¶	26 ± 3.6	80 ± 10

Rats were perfused with  $3 \times 10^{-8}$  molar tritiated noradrenaline (NA),  $10^{-4}$  molar cocaine (C) and adrenergic blocking agents for 10 min and the hearts were then assayed for noradrenaline and its metabolites. Results are expressed in  $\mu$ curies of noradrenaline or its metabolites per gram of heart  $\pm$  standard error of the mean. Five hearts were used in each group.

\* Deaminated catechols include 3,4-dihydroxy-mandelic acid and 3,4-dihydroxy-phenylglycol.

† O-Methylated deaminated metabolites include 4-hydroxy-3-methoxy-mandelic acid, 4-hydroxy-3-methoxy-mandelic aldehyde and 4-hydroxy-3-methoxy-phenylglycol.

‡  $P < 0.05$  compared with control hearts.

§  $P < 0.001$  compared with control hearts.

||  $P < 0.05$  compared with cocaine treated hearts.

¶  $P < 0.001$  compared with cocaine treated hearts.

\*\* Too low to be measured accurately in the presence of a large excess of unchanged tritiated noradrenaline.

In hearts perfused with tritiated noradrenaline alone almost all the radioactivity in the heart was present as unchanged tritiated noradrenaline, which confirms previous findings<sup>9</sup> (Table 1). Small amounts of the O-methylated metabolite tritiated normetanephrine and traces of tritium deaminated catechol metabolites were found. When cocaine was added to the perfusing medium to block the uptake of noradrenaline into sympathetic nerves, the accumulation of tritiated noradrenaline was reduced to less than 10 per cent of that in control hearts. In the presence of cocaine, however, the concentrations of tritiated normetanephrine were generally higher than those in control hearts (Table 1). In control hearts tritiated normetanephrine represented only 5 per cent of the total radioactivity, but in the presence of cocaine, tritiated normetanephrine accounted for about 50 per cent of the total radioactivity. Similar increases in the relative importance of O-methylation in the inactivation of tritiated noradrenaline in the heart have been reported under conditions in which the uptake of noradrenaline into sympathetic nerves was diminished by surgical denervation of the sympathetic nerve supply<sup>10</sup> or in the tissues of immunosympathectomized rats<sup>11</sup>. In the presence of cocaine, tritium deaminated catechol metabolites were reduced to 60 per cent of the control values. These findings are consistent with the hypothesis that the O-methylation of noradrenaline occurs at extra-neuronal sites, whereas deamination occurs at both intra- and extra-neuronal sites<sup>12</sup>.

When hearts were perfused with cocaine and adrenergic blocking agents, the amount of tritiated noradrenaline accumulating in the tissue was still further reduced (Table 1). Under these conditions, however, the concentrations of all the metabolites of tritiated noradrenaline were also markedly reduced. The  $\alpha$ -adrenergic blocking agents, phentolamine and phenoxybenzamine, reduced the concentrations of metabolites to levels only 5–25 per cent of those in hearts perfused with cocaine alone. The  $\beta$ -adrenergic blocking agents dichloroisoprenaline and pronethalol reduced all metabolites by about 60 per cent.

The reduced metabolism of tritiated noradrenaline caused by the adrenergic blocking agents occurred only in the intact tissue. When the drugs were examined as inhibitors of catechol-O-methyl transferase or monoamine oxidase in heart homogenates *in vitro*, using concentrations of tritiated noradrenaline and drugs similar to those in the perfusion experiments, the adrenergic blocking agents did not reduce the metabolism of tritiated noradrenaline by either enzyme.

These results indicate that adrenergic blocking agents can inhibit the extraneuronal metabolism of noradrenaline by preventing the access of noradrenaline to the metabolizing enzymes. Because both monoamine oxidase and catechol-O-methyl transferase are intracellular enzymes, the adrenergic blocking agents may act by preventing the substrate noradrenaline from entering the cells which contain these enzymes. It has been demonstrated that a specific transport mechanism exists for the entry of extracellular catecholamines into sym-

thetic nerves<sup>3,4</sup>; it is possible that the entry of noradrenaline into postsynaptic structures is also mediated by a specific transport mechanism. If the adrenergic blocking agents were to act at such a site, they could prevent the access of noradrenaline to metabolizing enzymes and possibly to intracellular adrenergic receptors.

The effect of a wide variety of pharmacological agents on the extraneuronal metabolism of tritiated noradrenaline is at present under investigation.

## CYTOLOGY

### Points of Attachment of Pachytene Chromosomes to the Nuclear Membrane in Mouse Spermatocytes

At the present time the only chromosomal element which is readily identifiable on electron microscopic examination is the "synaptonemal complex"<sup>1</sup> of the male primary spermatocyte. In the course of a study of the mode of attachment of this structure to the nuclear membrane in a variety of mammals, we noted that, in the mouse, two distinct types of endings were seen near the point of attachment. In one type the bivalent appeared to be condensed around the synaptonemal complex to form a heterochromatic "basal knob"<sup>2</sup> while, at the other type of ending, the complex was not surrounded by condensed material. The appearances are shown in the electron micrograph (Fig. 1) in which, by a fortunate chance, the entire length of the synaptonemal complex of a bivalent is seen in one section. Since it is now generally agreed that the mitotic chromosomes of the mouse are telocentric with truly terminal centromeres<sup>3,4</sup> and the heterochromatic regions of mouse spermatogenic autosomes are thought to be located adjacent to the loci of the kinetochores<sup>5</sup>,

Fig. 1. Primary spermatocyte from mouse testis. Electron micrograph  $\times 7,200$ . A, "Centromeric" end of bivalent. B, "Distal" end of bivalent. SV, sex vesicle.

there seems to be justification for identifying the attachment labelled A in Fig. 1 with the centromeric end of the pachytene chromosome and that labelled B with the distal end.

Suitably fixed and embedded mouse testis was then sectioned at between 200 and 300  $\mu$  and examined under the electron microscope and the attachments of the synaptonemal complexes to the nuclear membrane were recorded in 100 cells. Cells were only included in the series when the sex vesicle (SV in Fig. 1) was clearly visible. In 100 cells the number of centromeric (type A) ends encountered was 80, the number of distal (type B) ends was 91. The further observation was made that 68 of the 80 (85 per cent) centromeric ends were located in the half of the cell which contained the sex vesicle, and 79 of the 91 non-centromeric ends were situated in the other half.

The findings of the investigation therefore suggest that in the mouse primary spermatocyte at pachynema the centromeric and distal ends of the bivalents are separately identifiable and that the "pachytene bouquet" is formed by the clustering of the centromeric ends of the bivalents around the sex vesicle with the distal ends stretching to be attached in the majority of cases to the nuclear membrane of the opposite side of the cell.

### Fine Structure of Platyhelminth Sperm Tails

ELECTRON optical studies made during the late fifties led to a general acceptance of the 9 + 2 pattern in the axial filaments of cilia, flagella and sperm tails. In 1961 an exception to the universally accepted pattern was reported in the sperm tail of the trematode *Haematoloechus medio-plexus*<sup>1</sup>. The tail was found to contain one rather than two fibrils in the central unit, giving a 9 + 1 rather than the

9 + 2 pattern. Subsequently (1962), while commenting on the evolutionary stability of the 9 + 2 pattern, one author noted that "even the *Haematoloechus* observation can be explained as an unusual reaction of the central pair (and sheath) to the fixation procedure"<sup>2</sup>. Also in 1962, Klima<sup>3</sup> identified the 9 + 1 pattern in the sperm tail of the turbellarian *Dendrocoelum* and the 9 + 2 arrangement in the cilia of the flame cells—the first record of the two patterns in the same organism. In 1964 Silveira and Porter<sup>4</sup> reported the 9 + 1 pattern in the sperm tails of three other turbellarian species, *Dugesia trigena*, *Bdelloura candida* and *B. propinqua*, but they found the 9 + 2 pattern in the cilia. In 1966 four additional trematode species—*Gorgoderia amplicava*, *Cotylophoran cotylophorum*, *Alaria arisaemoides* and *A. mustelae*—were reported with 9 + 1 sperm tails<sup>5</sup>.

A model of the cross-section of a sperm tail (Fig. 1) can be described as follows: on the outside the enclosing plasma membrane (G) supports a system of microtubules (H) which vary in number from four to a maximum of thirty-six (ref. 1). The remainder of the cross-section is the axial fibre bundle which resembles a wheel; the hub is the single central filament (A) which is connected to the rim of nine doublet filaments (F) by spokes (E). Three distinct areas can be recognized in the single axial filament; the centre is a dense core (B) enveloped by a homogeneous cortex (C) of lesser electron density both of which are encased by a sheath the density of which is similar to that of the core. The diameter of the axial fibre bundle is 150  $\mu$ , while that of the entire sperm tail is approximately 200  $\mu$ .

The recognition that four turbellarian and five trematodian species have the 9 + 1 patterns in their sperm tails suggests that a similar pattern might exist in the remaining group of the platyhelminths, the cestodes. We have not come across any references to electron microscopy of the sperm tails of cestodes. Fortunately, however, in a paper concerned with the macromolecular structure of glycogen<sup>6</sup> there are micrographs of sperm tails of *Hymenolepis diminuta* which show the 9 + 1 pattern (ref. 6, Fig. 16). Thus, this finding—even though for a single species—extends the 9 + 1 sperm tail pattern into the cestodes. Interestingly enough, another micrograph in the glycogen study (ref. 6, Fig. 19) shows the 9 + 2 pattern in the flame cells of the same cestode.

The first reports of the 9 + 1 sperm tail pattern for both the trematodes<sup>1</sup> and the turbellarians<sup>3</sup> were for single species which were extended to other species<sup>4,5</sup> as a result of additional studies. The 9 + 1 fibrillar arrangement is very probably a normal pattern for the sperm tails of these animals. Similarly, the same may apply to the cestodes, especially in view of the close phylogenetic

Fig. 1. Generalized cross-section of a platyhelminth sperm tail.

relationship of the three classes. Studies of additional cestodian species are needed, however, before a definite conclusion can be reached. For the moment we can only conclude that the sperm tails of all platyhelminths studied by electron microscopy show a 9+1 pattern in the axial fibre bundle. It is interesting that the 9+2 pattern occurs in the axial fibre bundles in the extensions of flame and epithelial cells in the turbellarians<sup>3,4</sup> and the cestodes<sup>5</sup>, the only classes of the platyhelminths so far investigated.

### Chemical Composition of the Cell Wall of *Caryophanon latum*

THE "giant micro-organism" *Caryophanon latum* was first described by Peshkoff as the "missing link" between the blue-green algae and the bacteria. He isolated the micro-organism from cow manure near Moscow, noting its unusual morphology including "its long rod forms containing a varying number of nuclei"<sup>1</sup>. Others have since isolated this organism in England and in the United States<sup>2,3</sup>. Pringsheim and Robinow have described this micro-organism. *Caryophanon latum* Peshkoff as "a very large Gram negative, peritrichously flagellated bacterium of unusual structural complexity"<sup>2</sup>. On the other hand, Provost and Doetsch reported the organism to be a Gram positive bacterium, susceptible to egg-white lysozyme and able to form protoplasts readily<sup>4</sup>. The work described here was designed to obtain further evidence as to the bacterial nature of the micro-organism by analysing the isolated and purified cell walls of *Caryophanon latum* for its constituent amino sugars, amino acids and monosaccharides.

The method of analysis was that of Becker *et al.*<sup>5</sup> except that the organism was grown on cow dung extract agar, then gently rinsed into a beaker with 95 per cent ethanol, and the cell disruption was accomplished with a 'Heat Systems Sonifer'.

Our results showed large amounts of glucosamine, muramic acid, alanine, glutamic acid and lysine, typical of cell walls of Gram positive bacteria. Diaminopimelic acid, which often appears in place of lysine in the cell wall mucoprotein, was absent. No monosaccharides were found. These results provide further evidence of the bacterial nature of *Caryophanon latum*. Although the finding of a small number of amino-acids in the cell wall indicates a Gram positive nature, we found the organism to stain Gram negative.

This work was done in the Biology Department of Hamilton College. We thank Dayna McDaniel for the culture of *Caryophanon latum*.

## HAEMATOLOGY

### Erythropoietic Response of Bone Marrow Cells cultivated in Diffusion Chambers

It is well known that cultivation of bone marrow by traditional *in vitro* methods does not sustain normal morphogenesis for prolonged periods of time<sup>1-4</sup>, and although synthesis of DNA and haem and some erythropoietic activity have been demonstrated *in vitro*<sup>5-9</sup>, these processes are maintained only for extremely short periods.

An alternative approach to the *in vitro* method is the technique of cultivating haematopoietic cells in diffusion chambers in the peritoneal cavity of host animals. With this method it has been demonstrated<sup>10-12</sup> that mouse marrow cells divide, differentiate and undergo maturation in a much more normal fashion for a considerably longer period than in strictly *in vitro* systems. Attempts to demonstrate morphologically the effect of the humoral agent, erythropoietin, on erythropoiesis in chambers by myself and other investigators<sup>13,14</sup> have, however, been unsuccessful. In view of the ability to demonstrate morphologically erythroblasts in unstimulated marrow cultures<sup>10</sup>, two questions arose as to why marrow in diffusion chambers did not respond to erythropoietin. Had cells in the diffusion chambers become refractory to erythropoietin, or were the methods utilized to reveal a possible effect adequate? In an attempt to resolve these questions, experiments were devised in which modified diffusion chambers and a non-morphological end point for demonstrating erythropoiesis were used.

In the first experiment a well-type (solid bottom) diffusion chamber was used.  $15 \times 10^6$  cells from a pool of C57/bl-6 mouse marrow were placed in chambers containing 0.1  $\mu$ c. of iron-59 and 0.1 ml. of either saline, normal serum or serum rich in erythropoietin. The latter was obtained from mice which had been bled 12 h earlier. Chambers sealed by membranes with a pore of 0.3  $\mu$  diameter were placed into the peritoneal cavity of normal mice. At intervals after implantation, chambers were taken from animals and cells were removed by treatment with hyaluronidase. Cells were washed three times with sterile saline to eliminate unincorporated iron-59 and were assayed for cellular incorporation of iron-59 in a well-type scintillation counter. The results obtained are summarized in Table 1, and are expressed in terms of incorporation of iron-59 as a percentage (10<sup>6</sup>) of the original amount of iron-59 in the chamber. Values for the saline and normal serum were essentially the same and are presented as pooled controls. Within 24 h there was seven times as much incorporation of iron-59 in those cells cultivated in serum rich in erythropoietin as in the control group. By day 3 incorporation of iron-59 in the cultures rich in erythropoietin reached a maximum value approximately four times greater than on day 1 and fifteen times greater than the controls. A drop in the incorporation of the isotope was noted between days 3 and 5 and between days 7 and 9. The value on day 9 is essentially the same as that on day 1 and still represents a fivefold increase over the controls.

The data obtained indicate that precursors of erythrocyte are present in diffusion chambers which are capable of responding to an erythropoietic stimulus. The failure to demonstrate a cumulative increase in incorporation of iron in the group with serum rich in erythropoietin could result from the utilization of erythropoietin by erythroid precursors which has been suggested<sup>15</sup>, or from a depletion

Table 1. INCORPORATION OF IRON-59

	1	Days after Implantation			
		8	5	7	9
Serum rich in erythropoietin	29.0 (6)*	100.7 (8)	39.5 (6)	47.3 (6)	24.5 (6)
Controls	4.2 (12)	6.6 (12)	8.8 (12)	8.7 (12)	5.0 (12)

The percentage of iron-59 in each chamber is multiplied by 10<sup>6</sup>.

\* Figures in parentheses denote the numbers of animals used.

of the precursor(s) on which erythropoietin acts. The decreased incorporation between days 3 and 5 and 7 and 9 in the group rich in erythropoietin suggests that a cyclic destruction of cells containing iron-59 may occur and be followed by loss of the isotope by diffusion out of the chambers.

The possible reason for the failure to demonstrate increased erythropoiesis in chambers bound by double membranes is derived from the results of a second series of experiments. Bone marrow cells suspended in saline with identical amounts of iron-59 were placed in well-type diffusion chambers, but were separated from serum rich in erythropoietin and from normal serum by membranes. These chambers were treated in the same fashion as the previous experiment. No effect of serum rich in erythropoietin was found. This suggests that erythropoietin even if present in the peritoneal cavity of host animals is inactivated when it passes through the membranes. This is substantiated by the demonstration that erythropoietically active urine is rendered inactive when sterilized by passage through 'Millipore' membranes<sup>18</sup>.

In addition to demonstrating the response of cultivated bone marrow cells to an erythropoietic stimulus, these results also suggest that the cessation of erythropoiesis in chambers bound by double membranes by its inactivation when diffused through the membranes may leave more stem cells in the implanted marrow free to differentiate into other cell types. This would account for the length of time granular-cytopoiesis ensues in chambers and for the numbers of histiocytes which eventually appear with time of cultivation<sup>19</sup>.

### Effect of Prolonged Exercise on Platelet Adhesiveness

It has been established that changes in platelet adhesiveness occur in a variety of physical and physiological conditions. A close investigation of the various physical conditions that affect adhesiveness showed considerable variations in the degree of adhesiveness in eighteen identical observations on the same subject<sup>1</sup>; there was also slight increase in adhesiveness after feeding. Many methods have been devised to measure stickiness of platelet, and there has been considerable variation in the observations made. This could mean that different methods are influenced by a number of factors concerned in adhesiveness<sup>2</sup>. We have investigated the effect of prolonged exercise on platelet adhesiveness. The study

was carried out on a group of sixty healthy young adults who were walking from London to Brighton, about 50 miles. The exercise lasted for about 20 h.

Platelet adhesiveness was measured using two techniques in parallel, the adenosine diphosphate (ADP) method<sup>3</sup> and a 'Celite' method (diatomaceous earth)<sup>4</sup>; the results before and after exertion have been compared in forty-five subjects.

Adhesiveness was recorded on fifty-one subjects in the 2 weeks before the exercise and on nine subjects 2-3 weeks after the walk. Forty-five of the walkers completed the 50 miles and the adhesiveness was measured immediately on arrival.

The subjects were not anaemic and their platelet counts were within normal limits. Blood was taken from a vein in the antecubital fossa using a disposable syringe and needle and by a standard technique in each case. Aliquots of 2 ml. of blood each were added to polystyrene bottles (2.5 in. × 1 in.) containing 2.4 mg of ethylenediamine tetraacetic acid (EDTA) and 2 mg of heparin, respectively. This gave concentrations in the blood of more than 4 mmolar EDTA and 1 mg/ml. of heparin. The platelet counts were made as described previously<sup>5</sup>. Independent observers took the average of duplicate counts, which were repeated if there was a discrepancy of more than 15 per cent. All tests were carried out at room temperature. The specimens were mixed on a Matburn wheel at 30 r.p.m. In Eastham's method 0.04 ml. of ADP was added to the heparinized blood (25 mg in 100 ml. of saline stored at -20° C in small aliquots). The blood was returned to the mixer for exactly 30 min, and then transferred to a similar polystyrene bottle containing EDTA and mixed for a further 20 min. Counts of this specimen were made and also of the corresponding original sample of EDTA, and the differences between the two were taken as the adhesive platelet count which was expressed as a percentage.

In the 'Celite' method, platelets were counted in the blood collected into EDTA, after mixing, then 0.5 g of 'Celite 560' was added and mixed for 45 min at 30 r.p.m. on the wheel.

The bottle stood for 2 min to allow the 'Celite' to settle and a further platelet count was performed from the 'Celite'-free upper layer. Platelet counts of EDTA blood samples allowed to stand in this manner showed no significant difference from counts of samples made immediately after mixing. The difference in the platelet counts before and after the addition of the 'Celite' was taken as the adhesive platelet count, which was expressed as a percentage.

By the ADP method (Fig. 1) before exercise the average adhesiveness was 62 per cent with a standard deviation of 7.8 per cent. We included in the normal range variation from the average mean of twice the standard deviation. After exertion the adhesiveness had decreased in thirty-

Fig. 1. Platelet adhesiveness before and after exercise, determined by the ADP method. ●, Male before exercise; ■, female before exercise; ○, male after exercise; □, female after exercise.

Fig. 2. Platelet adhesiveness before and after exercise, determined by the 'Celite' method. Symbols are the same as in Fig. 1.

three subjects, increased in twelve; thirteen of the former observations were lower than the normal range.

The differences between the results before and after exertion were analysed using Gosset's *t* test and found to show a significant fall in platelet adhesiveness ( $P < 0.001$ ).

By the 'Celite' method (Fig. 2) the average adhesiveness before exercise was 42.5 per cent with a standard deviation of 16 per cent. We took a normal range of twice this standard deviation.

After the walk, adhesiveness had decreased in thirty and increased in fifteen. The results from ten of those with reduced adhesiveness were below the calculated normal range. The difference between the observed adhesiveness before and after exertion was analysed. It was found that after the exercise adhesiveness was significantly reduced  $0.005 > P > 0.001$ .

The results for each technique indicated the same type of change in thirty-six of the forty-five subjects investigated. In twenty-seven, the platelet adhesiveness decreased when measured by both methods and in nine cases it increased. The remainder gave opposing results, but in each case the values fell within our normal range. There appears to be a reasonable correlation between the results of both procedures.

It is clear from these results that there was a fall in platelet adhesiveness in the majority of our subjects. In those persons in whom a rise was observed this was within our experimental range. No attempt was made to correlate the results with the sex of the walkers. Only five women are included in the series, and the significance of any difference of the adhesiveness of platelets would be difficult to interpret in such a small number.

There were several variable factors which are difficult to assess. No one undertook special training for the walk, but some were accustomed to more exercise than others, not, however, to regular exercise of a degree comparable with a 50 mile walk. It was impossible to control the amount or type of food and drink taken by the walkers just before or during the exercise, but questioning revealed that the diet was adequate in all cases and contained chiefly carbohydrate and fluids. Many of the people took drugs during the walk, usually paracetamol, but a few also took codeine or aspirin.

Our results are at variance with others<sup>6</sup> but may not be strictly comparable, because the type of exercise was not the same. In other investigations an increase in platelet adhesiveness was observed after volunteers had been subjected to almost exhaustive muscular exercise for 6 min. In the present tests the exercise was less severe but greatly prolonged.

It seems likely that the marked fall in platelet adhesiveness is the result of the change in environment of the platelets rather than any alteration in the platelets themselves. The platelet counts on the subjects before and

after the walk showed no definite pattern of change (twenty-nine were virtually the same, ten were raised and six were lowered). This would eliminate the possibility that after the exercise we were assessing an altered platelet population, caused by mobilization of platelets in the hyperdynamic state.

While counting the platelets after the exercise it was noted incidentally that the white cell count appeared to be raised to approximately twice the normal in each case. It was probable that there was prolonged increase of adrenaline during the stress of this continuous exercise. Adrenaline has produced increased platelet adhesiveness *in vitro*<sup>7,8</sup>. An increased platelet count associated with increased adhesiveness after adrenaline has been described<sup>9</sup>. In view of these observations, our findings suggest that physiological effects of the prolonged exercise have nullified changes that might have been expected, because of prolonged production of adrenaline.

Although food was taken during the walk, endogenous glucose was probably mobilized because of the severity of the exercise. A fall in platelet adhesiveness when endogenous glucose was mobilized by smoking has been shown<sup>10</sup>. Other changes in the blood may also have contributed to the alteration in the adhesiveness. A relationship between platelet stickiness and changes in fatty acids has been shown *in vitro*<sup>11</sup>.

We thank the Clinical Research Sub-committee, Charing Cross Hospital, for financial support. This work was made possible by the students and staff who took part in the "Brighton walk", and by J. F. Horley, who allowed us facilities in his laboratory at the Royal Sussex County Hospital, Brighton. Miss P. Turnbull, of the Photographic Department of Charing Cross Hospital, photographed the figures.

## Erythropoiesis in the Regenerating Spleen

Till and McCulloch<sup>1</sup> have observed that cells obtained from mouse bone marrow can produce colonies of cells with haematopoietic competence when injected into the spleens of irradiated mice. Their findings verify the earlier reports of other workers, notably Jacobson *et al.*<sup>2</sup> and Cole *et al.*<sup>3</sup>, who observed that the partial shielding of either bone marrow or spleen, or the injection of homogenates of these tissues from normal animals into irradiated animals, would prevent deaths normally associated with the haematopoietic syndrome.

More recently McCulloch<sup>4</sup>, using an ingenious split-dose technique to label the chromosomes of donor stem cells, has found that individual spleen colonies derived from a single clone can produce blood cells of more than one line. Differentiating cells of erythrocytic, granulocytic, and megakaryocytic lines were found side by side within the same spleen colony.

While this work appears to indicate that individual stem cells are not completely predetermined to one specific line of differentiation, certain questions about the effects of the source of the donor tissues on the subsequent behaviour of the stem cells in the host remain outstanding. For example, McCulloch and Till<sup>6</sup> have reported that ten times as many spleen cells as marrow cells are required to obtain the same number of colonies. Numerous workers<sup>6</sup> including ourselves have observed that spleen nodules can vary greatly in size, but may still be easily divided into two extreme groups of large and small nodules. In addition, Gurney<sup>7</sup> reports that the large colonies seem to develop predominantly along erythroid lines, while the small colonies tend to develop neutrophils, and that the injection of erythropoietin or leucopoietin can affect the relative numbers of large and small colonies.

We have attempted to investigate the effect of the source of donor tissue on erythropoiesis in regenerating spleens containing colonies derived from either spleen or bone marrow. We used an iron-59 labelling technique<sup>8,9</sup> to measure erythropoiesis. There is often a wide divergence in colony size within the spleen and between spleens, and we concluded that the spleen-weight method recommended by Popp *et al.*<sup>10</sup> would be a more reliable method of measuring spleen regeneration than adding up the number of colonies. This method also allowed us to compare directly the erythropoietic ability of the regenerating spleen with that of the spleens of normal animals and of untreated, irradiated control animals.

For these experiments Swiss mice were irradiated with 950 rads, using a 250 kVp. X-ray unit. In each experiment, the age of the donors was identical with the age of the recipients. To reduce deaths due to bacteraemia, all the animals were fed neomycin *ad lib.* in their drinking water for 5 days before irradiation. Combiotic was also injected with the cells at a concentration of 0.003 mg/mouse. The spleen or bone marrow cells were derived from pooled tissue homogenates obtained from two or more animals, suspended in normal saline, and injected into the tail vein (0.5 ml. per animal). The irradiated controls were sham-injected with saline and combiotic only.

In the experiments reported in Table 1, all the mice receiving donor tissue were given  $10^8$  cells within 4 h of the completion of X-irradiation. Female mice 8–10 weeks old were used and the period between irradiation and killing was 10 days. 24 h before killing, each mouse received 0.5  $\mu$ c. of iron-59 as ferrous chloride by intra-peritoneal injection. All the spleens were immersed in Bouin's solution after excision to make the nodules more easily visible. All weights were determined as wet weights. All spleen weights were normalized to the approximate weight of the normal spleen (100 mg). The average weight of the regenerating spleens was roughly 60 per cent that of the normal spleens, regardless of the source of donor tissue. The spleens of the irradiated control mice were approximately 20 per cent of the normal controls in weight. Before assaying for iron-59 content, and before being immersed in the fixative, the spleens were washed thoroughly in normal saline. The uptake of iron-59 was measured by a scintillation counter equipped with a pulse-height analyser and an automatic sample changer. The results are given as mean per cent uptake of iron-59 per 100 mg of spleen tissue, for each experiment. The results in the last line of Table 1 are the combined

Table 1. PERCENTAGE UPTAKE OF IRON-59/100 MG OF SPLEEN

Experiment No.	Controls (not irradiated)	950 rads + spleen	950 rads + bone marrow	950 rads only
1	3.15(9)*	—	—	1.61(8)
2	2.99(7)	—	9.69(15)	2.30(5)
3	4.12(5)	—	10.74(7)	1.53(4)
4	3.01(7)	4.17(5)	—	2.08(8)
5	3.85(6)	6.48(15)	—	1.91(3)
Mean	3.37 $\pm$ 1.12 (34)	5.90 $\pm$ 1.51 (20)	10.03 $\pm$ 4.34 (22)	1.89 $\pm$ 1.22 (28)

\* Numbers in parentheses are numbers of animals in each part of the experiment.

Table 2. PERCENTAGE UPTAKE OF IRON-59/100 MG OF SPLEEN

Experiment No.	Controls (not irradiated)	950 rads + spleen	950 + bone marrow
6	2.69 $\pm$ 1.43 (8)	2.57 $\pm$ 1.67 (5)	6.60 $\pm$ 2.41 (8)

means for all animals in each column, together with a standard deviation computed from the uptake values of individual animals.

The results show that while spleens containing colonies derived from bone marrow tissue were more active in erythropoietic than normal spleens by a mean factor of 3.1, those with colonies derived from spleen cells were more active by a mean factor of only 1.8. Both types of regenerating spleens and the normal spleens showed significantly more iron-59 activity than the irradiated controls.

In the second experimental group (Table 2), we were concerned with both the effects of age and the relative number of colony forming cells in the spleen and bone marrow<sup>5</sup>. In these experiments female mice 4–6 months old were used. The mice receiving bone marrow were given  $4 \times 10^6$  cells; those receiving spleen were given  $4 \times 10^7$  cells, in accordance with the colony-forming ratios given by McCulloch and Till<sup>6</sup>. In this experiment also the ages of the donors matched those of the recipient animals. The other conditions were also similar to those of the preceding experiments.

The results show that the relative erythropoietic activity of colonies derived from spleen and bone marrow is not a function of the number of cells administered. Moreover, it appears that in addition to a general lessening of erythropoietic ability with age in all groups, regenerating spleens derived from spleen cells no longer have the ability to exceed the erythropoietic activity of the spleens of normal animals (as was seen in the younger animals in Table 1).

We conclude from these results that colonies derived from bone marrow tissue are more effective erythropoietically in regenerating spleens than those derived from spleen tissue. It also appears that age is an important factor in determining erythropoietic activity in the regenerating spleen. The results show that by the age of 4–6 months the capacity for erythropoiesis of tissue from regenerating spleen is no longer greater than that of normal mice. On the other hand, though reduced, the erythropoietic ability of tissue derived from bone marrow is still markedly greater than that of normal spleen. These findings are strong evidence that the source of the donor haematopoietic tissue influences its subsequent initial activity in the irradiated host.

## IMMUNOLOGY

## Simple Method for Preparation of Haemagglutinating Arbo-A Virus Antigens from Brains of Suckling Mice

HAEMAGGLUTINATING (HA) arbovirus antigens are usually prepared from the brains of suckling mice. This preparation is frequently performed by the acetone and ether extraction method of Casals and Brown<sup>1,2</sup>. That method is rather long and costly, however, so that the development of a method which avoids these disadvantages seems desirable. We thought that treatment of infected suckling mouse brains with 'Tween 80' and ether could provide a method by which HA antigens could be obtained simply. This assumption was based on our finding<sup>3</sup> that a haemagglutinating component can be released from the viral envelope of a group A arbo virus (Sindbis) by treatment of "complete" and "incomplete" virus with 'Tween 80' and ether.

In the work reported here the following three methods for the preparation of HA antigens were compared. (Method I) Acetone and ether extraction by the method of Casals and Brown<sup>1,2</sup>. (Method II) Infected suckling mouse brains were frozen and homogenized with 9 volumes of chilled borate buffer, pH 9.0. The homogenate was centrifuged for 5 min at 3,000 r.p.m. in the cold. The supernatants were collected and 'Tween 80' was added to give a concentration of 2 per cent; in addition, peroxide-free ether was added in an amount equal to the volume of the supernatant. The mixture was shaken for 20 min at room temperature and again centrifuged for 10 min at 5,000 r.p.m. in the cold. After centrifugation, the water phase was collected and residual ether was removed by bubbling nitrogen through the mixture. By this method, a supernatant of a homogenate of infected suckling mouse brains which had been treated with 'Tween' and ether furnishes the HA antigen. (Method III) To 1 volume of frozen and infected suckling mouse brain 9 volumes of borate buffer, pH 9.0, 10 volumes of ether, and 'Tween 80' in an amount to give a final concentration of 1 per cent were added. The whole mixture was homogenized, centrifuged in the cold for 5 min at 5,000 r.p.m., and the turbid water phase was collected and treated with nitrogen as described above. This method can be carried out very rapidly because homogenization and treatment with 'Tween' and ether are carried out in a single step.

Three day old mice were infected with a mouse-adapted Sindbis virus strain AR86 and 6 day old mice with a Western equine encephalitis (WEE) virus strain. Inoculation of the mice and removal of their brains were carried out as described by Clarke and Casals<sup>2</sup>. Infectivity of the HA antigens was assayed by the plaque technique using chick embryo cells<sup>3</sup> (P.F.U., plaque forming units). The techniques described<sup>3</sup> were applied in the haemagglutination and haemagglutination-inhibition tests carried out in test-tubes. Haemagglutination was allowed to proceed at 37° C, usually at a pH of 6.0. The haemagglutination titre is expressed in HA units/ml.

Table 1 summarizes the results of experiments with WEE and Sindbis viruses. It can be seen that in the case of WEE virus methods II and III resulted in a yield of haemagglutinin sixteen times greater than that given by method I; in the experiment with Sindbis virus, the yield was four times as great as for method I. HA antigens obtained by method III contained more P.F.U. than those of methods II and III. Similar results were

obtained in additional experiments. The specificity of the HA antigens of all three methods was determined by the haemagglutination-inhibition test. Haemagglutination-inhibition titres of a virus specific anti-hyperimmune serum were the same for 4 HA units of the three different preparations. It should be emphasized that there were slight differences between the antigens of methods I, II and III with regard to the optimal pH values of the HA reaction. Optimal condition for HA reaction of a WEE antigen obtained by method I was at pH 6.0, whereas WEE antigens of methods II and III gave highest titres at pH 5.8 and 6.0. With Sindbis virus, pH optimum for an antigen of method I was 6.0, and for antigens of methods II and III optimum pH was 6.0 and 6.2. Stability of antigens at 4° C was tested over a period of 18 days. Antigens of method I remained stable during this period, whereas haemagglutinating activity of antigens of method II decreased twofold and of method III sixteenfold.

These results suggest that methods II and III are superior to the acetone and ether extraction method I, in that they can be carried out more rapidly, with less material, and give higher yields of haemagglutinin and contain less infective units. They are inferior to antigens of method I with regard to their stability. For practical use, preparation of HA antigen according to method II is recommended, because it is more stable and less infectious than antigen prepared by method III.

Fig. 1. Distribution of haemagglutinating activity after caesium chloride density gradient centrifugation of antigens obtained by method I (●—●); method II (×—×); method III (○—○); (●—●), distribution of infectivity of the antigens obtained by method I ( $\rho$  = buoyant density).

Finally, the distribution of haemagglutinating activity after caesium chloride density gradient centrifugation of antigens obtained by methods I, II and III was determined. For this purpose, antigens prepared by methods I and III were diluted 1:2, and antigens prepared by method II were diluted 1:4, in borate buffer, pH 9.0. The diluted antigens were mixed with the required amounts of caesium chloride. Centrifugation, sampling of fractions and density determinations were performed as described previously<sup>3</sup>. Fig. 1 shows the results of such an experiment. The greatest haemagglutinating activity of antigens from methods II and III was found in a fraction with a buoyant density of 1.270. Apparently this activity was shown by a component which was also isolated by treatment of purified "complete" and "incomplete" Sindbis virus with 'Tween 80' and ether<sup>3</sup>. On the other hand, haemagglutinating activity of a method III-antigen was distributed in a density range of 1.270–1.225. This indicates that haemagglutinating activity of an antigen obtained by extraction with acetone and ether is associated with components of different densities. One of these components, detected in the 1.270 fraction, seems to be identical with the above.

Table 1. HAEMAGGLUTINATION AND INFECTIVITY TITRES OF PREPARATIONS OBTAINED BY METHOD I, II, III AND IV

Virus	Method	HA units/ml.	P.F.U./ml.
WEE	I	1,280	$5 \times 10^4$
	II	20,480	$7 \times 10^4$
	III	20,480	$3 \times 10^4$
Sindbis	I	320	$10^4$
	II	1,280	$< 4 \times 10^4$
	III	1,280	$< 4 \times 10^4$

mentioned haemagglutinin. Another haemagglutinating component of the acetone and ether preparation was associated with infectivity and was detected at a density of 1.247, suggesting that this component represents "complete virus particles" which have not been destroyed by the acetone and ether extraction procedure.

### "Normal" Antibodies which react with Heterogenetic Bacillary Antigen

STUDIES have been reported of a bacteriogenic transfusion reaction<sup>1</sup> in which the recipient's red cells became poly-agglutinable, apparently as a result of the presence of a species of *Bacillus* in the donor bottle which was capable of altering erythrocytes *in vitro* in a similar way. It was suggested that modification of the cells by bacterial antigen with subsequent haemolysis by "normal" anti-bacterial antibody might provide the mechanism for such reactions. In further investigations<sup>2</sup>, heterogenetic antigens from various genera and species of Gram-positive bacteria were examined, some prepared by the methods of Rantz<sup>3</sup> and Neter<sup>4</sup>, and were shown to react with anti-bacterial antibodies found in normal human sera. Crude preparations of at least two such antigens, present in bacilli and in *Staphylococcus aureus*, as well as a third, found only in *Streptococcus*, reacted with antibodies in sera of practically 100 per cent of apparently normal persons. Whether this high frequency of reactivity resulted from the cumulative effect of several antibody specificities or from a single specificity was re-examined with purified antigen.

Antigen was extracted from 72 h cultures of *Bacillus* sp. No. 372-56 by boiling, as described previously<sup>2</sup>. The organisms and debris were removed by centrifugation and the supernate was mixed with ten volumes of acetone, which was decanted after the antigen had been precipitated. Precipitates were dried to remove traces of acetone and redissolved in 0.85 per cent solution of sodium chloride, buffered at pH 6.7 with phosphate salts. These antigens were tested<sup>2</sup> for their content of hexose and their ability to modify erythrocytes. Washed human group O red cells were mixed with twenty volumes of an optimal concentration of antigen, incubated at 35° C for 30 min, washed again, and resuspended in buffered saline solution (pH 6.7) at a concentration of 2 per cent. Tests were conducted on one hundred consecutive normal blood donor sera by mixing 0.05 ml. of serum with 0.05 ml. of modified cell suspension, incubating the mixtures at 5° C for 30 min, centrifuging lightly, and reading the results microscopically. Duplicate tubes were incubated at 37° C for 1 h, the cells washed, and tested with antiglobulin serum. Each donor serum was also tested against control cells which had been treated with buffered saline instead of antigen solution. Reactive sera of known titre were included in each test protocol to control the sensitivity. Of the one hundred normal donor sera, eighty-six produced agglutination of modified cells in saline and ninety-seven yielded positive results by the antiglobulin test (Table 1). Two sera failed to react by either procedure. An attempt

to demonstrate blocking by these two sera failed, although previous work<sup>2</sup> has indicated that blocking may be produced by anti-streptococcal human sera which react with the NSS heterogenetic antigen of Rantz<sup>3</sup>, and some of the other twelve non-agglutinating sera appeared to exhibit a slight blocking effect.

60 min at 56° C	—	—	—	—	—	—

The reactivity of normal human sera with bacillary carbohydrate antigen was associated with the gamma globulins when sera fractionated by certain electrophoresis were tested against modified erythrocytes. These antibodies were partially absorbed by bacillary cell suspensions (Table 2). Some of the saline-active antibodies were heat-labile at 56° C (Table 3) if heated for more than 30 min, and the reactivity of sera containing incomplete antibodies was removed even more readily. The instability of these antibodies was confirmed by demonstrating a loss of reactivity after treatment with 2-mercaptoethanol.

Although agglutinins for the purified carbohydrate antigen from bacilli were demonstrated in only 86 per cent of the sera, 98 per cent were reactive in either one or both of the saline and antiglobulin tests. The possibility that this difference was more quantitative than qualitative has not been completely ruled out, although the sensitivity of the testing procedure was at least as great as that of previous tests with crude antigen.

This work was aided by a grant from the National Institutes of Health, U.S. Public Health Service.

Donor sera were obtained through the courtesy of Dr. T. D. Stevenson and Mrs. Anna J. Denzel of the Transfusion Service, University Hospital, Ohio State University.

## GENETICS

## Incompatibility Alleles of Cocoa

Knight and Rogers<sup>1</sup> found five incompatibility alleles in the *Theobroma cacao* clones Parinari 7 (alleles 1 and 5), Parinari 35 (3 and 5), and Nanay 32 (2 and 4). Allele 1 is dominant to the others; alleles 2 and 3 are independent but are dominant to allele 4, which in turn is dominant to allele 5. A tree is incompatible both as male and female with another which has the same dominant allele; a tree carrying two independent alleles is incompatible with trees carrying either in the absence of others dominant to them.

Cope<sup>2</sup> found that the reaction is associated with failure of male and female gametes carrying the same dominant (or independent) allele to fuse. An ovary containing "non-fusions" aborts, although normal fusion may have occurred in the majority of the ovules. The recessive alleles of Parinari 7 and Parinari 35 are distinct, but this does not alter Knight and Rogers's basic theory. Cope's results also indicate that the dominant allele of Scavina 12, which he termed 0, is independent both of Knight and Rogers's allele 1, and of the incompatibility allele I found in the Trinitario population.

Further work at Tafo<sup>3</sup> has extended the range of known alleles, and has shown that (a) an allele may be independent of two other alleles, one of which is dominant to the other, and (b) some incompatibility alleles are recessive to the allele for self-compatibility. An example of (a) is provided by an allele present in Iquitos 47 and Iquitos 60, which is independent of both allele 1 and allele 2 although allele 1 is dominant to allele 2. A further example is provided by the Trinitario allele I, which in addition to being independent of allele 0 is independent of alleles 2 and 3. An example of (b) is allele 4; thus a progeny obtained by crossing a tree known to carry alleles 1 and 4 to a self-compatible Amelonado tree consists of self-compatible and self-incompatible trees in equal proportions, and the self-incompatible trees carry allele 1. Similar evidence is provided by progenies obtained by crossing self-compatibles with trees carrying alleles 2 and 4 and alleles 3 and 4. Further, progenies obtained by crossing trees carrying allele 4 together with the recessive allele of Parinari 7 to self-compatible trees have proved to be fully self-compatible, which indicates that the recessive allele of Parinari 7 is also recessive to self-compatibility. All alleles dominant to self-compatibility are dominant to those recessive to self-compatibility, and where one allele is dominant to a second, all alleles dominant to the first are also dominant to the second.

The Trinitario incompatibility allele I usually seems absolute in its effects; thus Voelcker<sup>4</sup> reported only one set (persisting at least 14 days) from 245 incompatible pollinations in Trinidad, and I obtained only one apparent set, which did not persist to maturity, from 300 self-pollinations on the Ghana Trinitario clone E1. Some of the alleles found in Amazon cocoa, however, may not be completely effective. Low rates of setting were obtained after self-pollination of some introduced (supposedly incompatible) Nanay clones, and investigation of introduced progenies suggests that the recessive allele carried by Nanay 31 is particularly inefficient.

Many of the data on which this report is based were collected by R. Knight and H. H. Rogers, and I am indebted to them for advice.

## PATHOLOGY

## Villous Atrophy and Coccidiosis

MEDICAL gastroenterology has advanced considerably since the introduction of a biopsy technique which permits histological examination of the intestinal mucosa<sup>1-4</sup>. The use of this procedure, and work on the determination of epithelial turnover times<sup>7,8</sup> in the intestine of mammals, has given impetus to the study of villous atrophy (maturation arrest<sup>5</sup>) in patients suffering from malabsorption syndromes.

In recent pilot experiments at Weybridge an attempt has been made to apply these findings to a study of the pathogenesis of infection with species of *Eimeria* in domestic animals. *Eimeria acervulina* and *E. crandallis* inhabit the small intestine of the fowl and sheep respectively and, apart from the first generation schizont of the latter species, all stages are confined to the epithelium<sup>9</sup>. My own observations (unpublished) have confirmed this.

Two-week-old coccidia-free chicks were infected with 80,000 sporulated oocysts of *E. acervulina*, and birds were killed by intra-cardiac barbiturate injection at 24-h intervals after infection; uninfected birds acted as controls. The intestine was injected *in situ* with Serra's fluid. Stained paraffin sections were examined under the light microscope and the tissues measured by a method similar to that used by Shiner *et al.*<sup>11</sup>. Similarly, 4-week-old cross-bred coccidia-free lambs were infected with 2,500 or 250,000 sporulated oocysts of *E. crandallis* daily for seven days. Following autopsy on the seventh day of the patent period, the tissues were examined in a manner similar to that described for the chicks.

Sections of intestinal mucosa showed that after the invasion of the epithelium the parasites "ride" in the host cells, so that "trains" of parasites can be observed proceeding up the villus. This was most marked by day 4, when maturing oocysts were seen at the tips of villi with later generations of schizonts travelling behind them, lower down on the villus.

Tissue measurements of the intestine of infected chicks showed that the ratio of villus height to total mucosal thickness gradually falls until by day 4 of the infection this parameter is most severely depressed (Fig. 1). This is the period in the infection when there is a maximum invasion of host cells by the parasitic stages.

Fig. 1. Ratio of villus height to total mucosal thickness.

Fig. 2. Depression in the villus height/total mucosal thickness ratio in the lower ileum compared with the upper ileum and duodenum.

Infections with *E. crandallis* in lambs were confined to the lower ileum, and it was this part of the intestine which also showed villus atrophy. Fig. 2 shows the depression in the villus height/total mucosal thickness ratio in the lower ileum compared with the upper ileum and duodenum. No parasites were found when this ratio was similar to that of the uninfected control animal. Thus, seven consecutive daily doses had provided constant parasitic invasion of the epithelium for several days, and this had produced all the features of villus atrophy.

Experimental infections with *Eimeria* are commonly single dose studies, but in the field continuous acquisition of infective oocysts occurs. It is, therefore, suggested that multiple dosing will give a more accurate picture of the pathogenesis of small intestinal coccidiosis, and tissue reactions of the type mentioned here could be a useful parameter of infection. Nematodes can produce a similar effect<sup>6,12</sup> and, because most domestic animals at some time experience clinical and subclinical intestinal parasitism, veterinary interest might be profitably directed to this field of pathology.

It has been shown that the turnover time of intestinal epithelium becomes shorter as the host becomes smaller<sup>7</sup>. At the same time, studies with *Eimeria* have suggested that the pre-patent period of a species has the same relationship to the size of host<sup>8</sup>. It is interesting to speculate whether this represents a manifestation of host-parasite adaptation.

## Milk Allergy in Infant Germ-free Rabbits

THE observations reported here were made in the course of attempts to establish a colony of germ-free rabbits for nutritional investigations. The infant rabbits were delivered by hysterectomy either into Gustafsson germ-free isolators or, as controls, into a conventional environment in which the physical conditions simulated as nearly as possible those inside the isolators. The diet was an aqueous dispersion of 12.5 g whole dried milk, 5 g calcium caseinate and 1 g vitamin supplement in glucose in 100 ml. It was sterilized by an ultra-high-temperature process, which resulted in little loss of its nutrient value. It was offered to the rabbits twice daily, in flasks fitted with rubber teats through which they readily learned to drink.

In the conventional environment 50 to 70 per cent of each litter usually survived to weaning. Losses mainly occurred during the first week and, from gross examination, were apparently due to enteritis, lung congestion and, occasionally, severe aspiration of the diet. By comparison, the germ-free rabbits seemed in better general condition but mortality was higher. Towards the end of the first week of life apparently healthy rabbits died suddenly. Death usually occurred several hours after feeding and was often preceded by convulsions. On post-mortem examination lung congestion was frequently found. The condition bears some resemblance to the so-called "cot death" in human infants<sup>1</sup>. Germ-free rabbits that survived to the twelfth day almost invariably began to exhibit signs of shock immediately after feeding. The signs were at first confined to trembling, stretching and panting, but worsened progressively to convulsions and Cheyne-Stokes respiration accompanied by cyanosis. Often the animals appeared to recover completely, but collapsed again after the next feed until ultimately a shock proved fatal.

The observed effects were suggestive of a histamine-induced reaction. For evidence on this point a histological investigation was undertaken to determine the condition of the mast cells. Specimens of gut mesentery, omentum and pleura were fixed as spreads in 80 per cent ethanol and stained with 1 per cent aqueous toluidine blue.

Tissue mast cells are not prominent in the rabbit, but there are abundant coarsely granular, strongly basophilic blood leucocytes which, it has been suggested<sup>2</sup>, are physiologically equivalent; they are commonly referred to as mast leucocytes or blood mast cells. Such cells were obvious in the blood vessels of tissue spreads from all the unshocked rabbits examined, both conventional and germ-free. When stained with toluidine blue, the granules were a dense blue-black although there was occasionally slight metachromasy.

In germ-free rabbits that had died of or been killed during a "feeding shock" spasm, and in these animals alone, the mast leucocytes appeared to be undergoing massive degranulation (Fig. 1), and it is assumed that this represents rapid release of histamine. Many of the dispersing granules, both within and outside the cell, exhibited metachromatic staining, while the cell body stained a featureless pale blue. Other cells were wholly pale blue, agranular, and without an obvious nucleus; it is believed that these were completely degranulated mast leucocytes.

A characteristic feature of rabbit omentum is the presence of small condensations of non-lymphatic tissue known as "milk spots", or "tâches laiteuses". Typical cells are irregularly oval, with a large oval nucleus, and they have been variously described as relatively undifferentiated mesenchymal cells and as fixed macrophages. The cell body is usually largely filled with strongly basophilic material, giving the cells a smudgy, mucoid appearance (Fig. 2a). Occasionally it may be seen that this material is in the form of densely crowded granules which may be stained with nuclear fast red made up in aluminium

sulphate<sup>3</sup>. In those animals where the blood mast cells were rapidly degranulating, the taches laiteuses were inconspicuous and their basophilic cells almost entirely degranulated (Fig. 2b).

The physical signs, degranulating mast leucocytes (and possibly also the changes in the taches laiteuses), in the shocked germ-free animals suggest that they were undergoing an allergic reaction to some component of the diet, and it seems likely that the bovine milk proteins, or products formed from them during processing, were responsible. It is possible that the lung congestion seen in some of the week-old conventional animals was also a manifestation of allergy but they seldom, if ever, exhibited any other signs of shock.

The markedly increased sensitivity of the germ-free animals is not readily explainable. It may perhaps be

associated with their comparatively slower response to antigenic stimuli<sup>4</sup>. It could be the result of a stronger antigenic challenge, since the thinner intestinal wall generally observed in germ-free animals might permit the passage of large molecules to a greater extent or for a longer time than is usual in conventional infant animals. These possibilities are being investigated.

We thank our colleagues, Dr. R. Fuller for sterility checks of the germ-free animals, A. Turvey for histological assistance and D. A. F. Miles for care and feeding of the rabbits.

### Lethal Action of Sugars on Ascites Tumour Cells *in vitro*

FARE<sup>1</sup> described a protective activity against the induction of liver tumours in rats fed with 4-dimethylaminoazobenzene by the addition to the diet of a fraction of ox liver prepared as described by Maisin and Lambert<sup>2</sup>. The protective activity of this water-soluble preparation, which was obtained by acetone extraction of liver pulp de-fatted with ether, was closely associated with its content of glucose, the only sugar detected. The reports of Nakahara and Fukuoka<sup>3</sup> concerning a bovine liver fraction lethal *in vitro* to Ehrlich carcinoma cells in ascites form, and of Tsuda *et al.*<sup>4</sup> concerning the cytostatic properties of various sugars and related compounds, were therefore of interest. Experiments with ox liver fraction and with a number of sugars lead us to conclude that the lethal action is largely attributable to the production of an acid pH resulting from breakdown of those sugars which are metabolized by the cells.

Preliminary tests using the ox liver fraction, D-glucose, D-mannose, L-rhamnose and D-ribose were carried out according to the directions of Tsuda *et al.* In the absence of definite specifications in the communication, the sugars were dissolved in phosphate buffered saline (without calcium or magnesium) pH 7.2 and the cells gently agitated during the incubation-exposure period of 1 h. We were surprised to find that our results differed materially from those of Tsuda *et al.* in that only those cells incubated with our ox liver fraction were killed; those incubated with the sugars produced tumours after the usual period when inoculated into mice. It appeared from a survey of the sugars and allied compounds cited by them that only those which are readily utilized by cells gave the positive, lethal activity and that the mechanism might be associated with the production of lactic or similar acid metabolites. Repetition of the tests with sugars in buffered (pH 7.2) saline always resulted in the cells remaining viable, but the addition of lactic acid or DL-glyceraldehyde to the medium in place of the sugar was lethal. On enquiry, Dr. Nakahara informed us that his tests were made in unbuffered 0.09 per cent sodium chloride. A further series of tests on the compounds previously examined and other related substances in buffered and unbuffered solutions was made, when, in most instances, the results from the latter were in line with those of Tsuda *et al.* (Table 1). The quantities of sugars used in all tests were 10 mg/ml. and the buffer had a pH 7.2 and was 0.1 molar. With D-galactose and dihydroxyacetone, neither of which we found to be lethal to the cells, we were unable to confirm the effect noted by Tsuda *et al.* It is possible that our strain of ascites cells is not able to utilize these compounds, or possibly essential

In every test series, control cells, washed and incubated in saline, gave tumours in all five mice inoculated.

co-enzyme factors were more thoroughly removed in our initial washing of the cells.

It should be observed (Table 2) that the pH of the final supernatant from the cells was well above pH 6 in both these instances. Accordingly, measurements of the pH of the supernatants were made after incubation of cells in presence of sugars in buffered and unbuffered saline and, as might be expected, exposure to pH below 6.0 appears to be deleterious to the cells. This would occur most readily in those tests using unbuffered media containing the metabolizable sugars. The presence of "free" lactic acid itself appears to be toxic. Its addition to the substrate to give an initial pH of 6.3 resulted in cell death (Table 3). In the final fluid the pH had risen to 6.7, presumably by extraction of buffering substances from the cells. Other organic acids, for example, pyruvic, succinic and butyric, were similarly lethal. Even when incubated in buffered saline, pH 7.2 throughout, cells to which lactic acid had been added did not produce tumours (Table 3).

Table 3. LETHAL EFFECT OF "FREE" LACTIC ACID

Incubation medium	Initial pH	Final pH
Unbuffered saline + lactic acid 10 mg/ml.	6.2	7.2
Galactose + lactic acid*	6.3	6.7
Mannose + lactic acid*	6.3	6.7
Lactic acid added to buffered saline†	7.2	7.2

\* Lactic acid 10 mg/ml. in 0.09 per cent sodium chloride + 10 mg/ml. sugar.

† Lactic acid 10 mg/ml. in phosphate buffered saline, pH 7.2, 0.1 molar.

"Carcinostatic" action attributed to change in pH was also noted by Apffel<sup>6</sup> during incubation of Ehrlich ascites cells or *EL4* leukaemia cells in a medium containing a fraction derived either from liver or serum from which the protein had been removed. Loss of viability also resulted if the suspending fluid was adjusted to pH 5.5 with dilute hydrochloric acid.

We tried to demonstrate the material degradation of sugars such as glucose and mannose by analysis before and after incubation, using, for example, the "Folin-Wu" copper reagent, but this was unsuitable since comparable amounts of reducing metabolites were produced during the incubation which also reacted with the reagent. Using tetrazolium salt (2,3,5-triphenyl tetrazolium chloride, TTC) it was possible to demonstrate that such reducing products were present—an intense red formazan was produced in the cold by TTC with the supernatants only from the easily metabolizable sugars, thus correlating with the pH and viability tests (Table 4). It should be noted that no formazan reaction was observed after incubation with D-galactose.

## BIOLOGY

### Growth Rates in *Lolium temulentum* as influenced by Previous Regimes of Light Energy

THE relationships between the vegetative growth of single plants and the intensity of incident light have been extensively studied in various dicotyledonous species<sup>1,2</sup>, and less extensively in herbage grasses<sup>3,4</sup>. These and other investigations assessed plant growth in terms of relative growth rate (rate of increase in plant dry weight per unit of dry weight already present, RGR) and its components leaf area ratio (photosynthetic surface per unit dry weight, LAR) and net assimilation rate (rate of increase in dry weight per unit of photosynthetic surface, NAR). As in most other species, decreasing the amount of light incident on grass plants generally leads to decreased RGR for, although LAR increases in these conditions, this is more than offset by a fall in NAR.

The LAR built up at any given time depends on the previous expansion of leaf surface and rates of growth of stem and root in response to external environment, and therefore an instantaneous change in LAR, consequent on the transfer of the plant to a new light regime, is physically impossible. There is, however, a gradual adjustment of the photosynthetic surface and the distribution of weight in stem and root, and so of LAR. In contrast, NAR is in no way so dependent on a change in the physical conformation of the plant, and although the absolute rates of assimilation may be influenced by the

Table 1. EFFECTS OF CHANGE OF LIGHT INTENSITY ON DRY WEIGHT AND RGR IN *Lolium temulentum*

Ear emerg.—seed set (23–45 days)									± 0.0019

previous history of the plant<sup>5</sup> the NAR usually becomes completely adjusted to a change in light intensity in a few hours. It follows that the relative rates at which these two components of RGR adjust to a new light regime could influence growth during the transition period and could temporarily result in unexpectedly high or low rates of growth until the plant is completely adapted to the new conditions. An example of these interactions has been found in recent experiments on the effect of light intensity on particular stages of inflorescence development in *Lolium temulentum*; unusually high and low growth rates were found after the transfer of plants between contrasting light regimes.

Three germinated seeds of *Lolium temulentum* L. were planted in each of a number of 3 in. pots of 'Perlite' immediately the coleoptile was visible, and the pots held in a controlled environment cabinet (temperature, 23° C day/18° C night; photoperiod, 20 h; light intensity, 3.0 cal/cm<sup>2</sup>/h). After 10 days, when the first leaf was almost expanded, the pots were distributed to one of two contrasting light intensities (6.6 and 1.6 cal/cm<sup>2</sup>/h) at the same temperatures and photoperiod as the pretreatment. Reciprocal transfers of some replicates between the two light intensities were made at spikelet initiation (onset of reproduction) and ear emergence. The time intervals between the beginning of treatment and transfer at spikelet initiation were: high light, 11 days; low light, 13 days. In all there were eight treatments—two light intensities for each of three successive stages of development designated H/H/H, H/H/L, H/L/H, H/L/L, L/H/H, L/H/L, L/L/H, and L/L/L. Plants were collected at the beginning and end of each period of development in order to determine dry weights and photosynthetic areas. The photosynthetic areas measured included one side of leaf blades and the exposed surfaces of sheaths and stems; no areas were measured after the emergence of the ears. For the purpose of calculating NAR, all photosynthetic surfaces were assumed to be equally efficient. All plants received a complete nutrient solution three times a week.

The dry weight increments per plant during the stages of development were not just a function of the incident light energy (Table 1): thus, at the emergence of the ears, plants given L/H were as heavy as, if not heavier than, equivalent plants given H/H; and plants given L/L were heavier than plants given H/L. Similarly, after further transfers at ear emergence, plants given H/L/H, L/H/H or L/L/H were heavier than plants in continuous high light (H/H/H); and plants given H/H/L, H/L/L and L/H/L were only about as heavy as those in continuous low light (L/L/L). The RGRs illustrate these differences in more detail (Table 1). The rate of gain of dry weight in a particular light intensity differed by as much as 50 per cent after the first transfer, and by as much as 100 per cent after the second transfer, depending on the previous light regimes. The efficiency of utilization of light energy per plant was thus very different; for example, plants weighing about 500 mg were produced after 28 days at 6.6 cal/cm<sup>2</sup>/h, or after 13 days at 1.6 cal/cm<sup>2</sup>/h plus 16 days at 6.6 cal/cm<sup>2</sup>/h.

The separation of RGR into its two components NAR and LAR was possible for stages until the emergence of the ears (Table 2). There appeared to be no large effect of the previous light regime on the NAR of plants transferred to contrasting light conditions, although the NAR of plants in high light, after low light (L/H), was significantly lower than that of plants in continuous high light (H/H). This difference is similar to that reported by Björkman and Holmgren<sup>5</sup> and is in the reverse direction to that needed to account for the differences in growth rate already noted. In contrast, LAR was very dependent on the previous light regime. No attempt was made to calculate the mean LAR over the periods of development, and the data given in Table 2 are the LARs calculated for the beginning and end of such periods. In addition to the ontogenetic drift common to both light intensities<sup>4,6</sup>, a much greater LAR was always developed in the low than in the high light conditions. Furthermore, on transfer to a contrasting light regime, plants started their growth with an LAR characteristic of the previous conditions. It appeared that the approximately fortnightly duration of the growth periods was about sufficient for complete adjustment of LAR to the current light conditions. Nevertheless, the initial disparity in LAR between that appropriate to current conditions and that appropriate to previous light conditions would result in unusually high or low RGRs, when considered in conjunction with an NAR characteristic only of current conditions. It is still not clear how rapidly LAR can become adjusted to new light conditions. The period of 15–17 days in this experiment is similar to the estimate given elsewhere for another perennial grass<sup>4</sup>. In this experiment, adjustment of LAR on transfer to contrasting light conditions involved changes in the percentage of dry weight invested in root and leaf, as well as changes in the leaf area to leaf weight ratio. Clearly, some time must elapse for these changes to be completed.

It appears that unusually high or low rates of growth can be achieved, at least for short periods, by suitable alternation between high and low light intensities, and that this follows from the different rates at which NAR and LAR become adjusted to new conditions. If more were known of the magnitude and duration of these interactions between past and present environmental effects on LAR, it might be possible to achieve higher efficiencies of utilization of light by exposing plants to intermittent high and low light intensities, rather than to continuous uniform

Table 2. EFFECTS OF CHANGE OF LIGHT INTENSITY ON NAR AND LAR IN *Lolium temulentum*

## Control of Leaf Senescence by Growth Retardants

THE degradation of RNA, protein and chlorophyll is closely associated with the development of senescence in plant leaves<sup>1,2</sup>. Senescence is delayed by treatment with various growth regulators<sup>1-6</sup> which apparently stimulate RNA turnover and protein synthesis<sup>2,4-9</sup>.

In a recent account we reported that (2-chloroethyl) trimethyl-ammonium chloride (CCC) markedly stimulated the *in vitro* synthesis of polyribonucleotides<sup>8</sup>. At the same time, the loss of protein and RNA in plants subjected to drought and previously treated with CCC and phyto-kinin was retarded and the plants survived longer under these conditions<sup>9</sup>. These findings tended to indicate that CCC, like phytohormones<sup>1-7</sup>, may interact with proteins and nucleic acids in leaves and thus possibly retard senescence.

To test this aspect, bean plants (*Phaseolus vulgaris* var. 'Brittle Wax') were grown at 25° C in a growth room. Leaf disks 0.6 cm in diameter were punched from inter-veinal areas of primary leaves (6-10 days after germination) and placed immediately on Whatman No. 1 filter paper in Petri dishes of 9 cm in diameter.

The filter papers were moistened with 4 ml. of the respective solutions and the closed Petri dishes were kept in the dark at 25° C. Each day after treatment samples of four replicates were collected, each replicate being composed of five disks.

Chlorophyll was determined by Arnon's procedure<sup>10</sup>. The decolourized tissue was homogenized with 5 per cent trichloroacetic acid. The proteins of the acid-insoluble fraction were assayed according to Lowry *et al.*<sup>11</sup>.

In case of incorporation experiments<sup>12</sup>, individual leaf disks were shaken at 30° C in a 0.5 ml. solution containing 1 µc./ml. of <sup>14</sup>C-leucine (specific activity 155 mc./ml.). The disks were then washed thoroughly and homogenized with water. All homogenizing and washing solutions contained 0.1 normal <sup>14</sup>C-leucine. A portion of the homogenate was used to estimate the total uptake of labelled leucine. The remaining homogenate was treated with trichloroacetic acid (5 per cent final concentration) and after standing in the cold for 1 h it was filtered through 'Millipore' filters of 0.65µ pore size. After successive washings with large volumes of trichloroacetic acid and perchloric acid (1 per cent) the filters were dried and counted in a three-channel liquid spectrometer. Incorporation of carbon-14 into the acid-insoluble fraction continued linearly for about 90 min.

The changes of protein and chlorophyll in senescing leaf disks are recorded in Figs. 1-4. The levels of protein and chlorophyll dropped markedly during the experimental period. The growth retardants CCC and B-995 (*N,N*-dimethylaminosuccinamic acid) preserved protein and chlorophyll as did kinetin, even giving rise to a slight initial increase. The disks on water started to disintegrate after 5-6 days. During the same period the disks treated with the growth retardants remained relatively green and turgid.

The changes in protein during senescence were followed by parallel incorporation assays (Table 1). The incorporation with time of tagged leucine into acid-insoluble

Table 1. INCORPORATION OF <sup>14</sup>C-LEUCINE INTO THE ACID-INSOLUBLE FRACTION OF 6-DAY-OLD BEAN LEAF DISKS SENESEING ON CCC (IN C.P.M./DISK)

Day	Water	Bean leaf disks from:	CCC
0		21,000	
1	11,700		11,500
2	10,400		10,000
4	7,400		7,800

Individual leaf disks, after senescing on water and CCC from 0 to 4 days, respectively, were incubated for various intervals of time in solutions containing 0.5 ml. of <sup>14</sup>C-leucine (1 µc./ml.; specific activity 155 mc./mmolar). In the case of the disks senescing on CCC the incubation solution contained the same concentration of this material. Incubation was carried out, under vigorous shaking, at 25° C. In the table, values for a 3-h incubation period are recorded. After incubation the disks were prepared for counting as described in the text.

products in the disks treated with CCC and the disks senescing on water decreased at parallel rates.

It seems from the incorporation experiments that, since CCC does not enhance the incorporation of <sup>14</sup>C-leucine into proteins, it should somehow retard the rate of protein breakdown in order to account for the higher protein level in the leaf disks senescing on CCC.

The stimulation by CCC and kinetin of protein accumulation was further analysed by including actinomycin D in the experimental solutions on which the disks were senescing. Actinomycin D was expected to prevent the increase of protein synthesis—it did so during the first day (Fig. 1). On the other hand, in contrast to expectation<sup>7</sup>, actinomycin D accentuated markedly the delaying effects of CCC and kinetin on senescence during the following 3 days. These effects of actinomycin D will be discussed in a separate account.

Fig. 1. Retardation of protein breakdown in 6-day-old bean leaf disks by CCC, kinetin and actinomycin D. Concentrations were 100, 20 and 40 mg/ml., respectively. Actinomycin D was included in the Petri dishes in which the leaf disks were senescing.

Fig. 2. Retardation of protein degradation by CCC (50 mg/ml.) and B-995 (500 mg/ml.) in 10-day-old bean leaf disks.

Fig. 3. Preservation of chlorophyll by CCC (50 mg/ml), B-995 (500 mg/ml.) and kinetin (20 mg/ml.) in 6-day-old bean leaf disks.

Fig. 4. Protein and chlorophyll levels in bean leaf disks following treatment with different concentrations of CCC. 3 days after start of the experiment.

The losses of RNA and protein are considered to represent key factors in the senescence of leaves<sup>2,4,5</sup>. The decline in the levels of chlorophyll and proteins is retarded in different plants by phytochemicals<sup>1-5</sup>, auxins<sup>6</sup> or gibberellins<sup>7</sup>, respectively. These findings led to suggestions that senescence is closely linked with a hormonal regulation and maintenance of protein synthesis. The present finding that growth retardants bring about senescence responses similar to those brought about by phytochemicals may suggest that, as in other aspects, the maintenance of a proper balance between the chief groups of endogenous hormones is a prerequisite for the retardation of leaf senescence.

## Autoradiography of <sup>32</sup>P in Maize Roots

THE concentration of ions in the vascular system of a plant root may be very much higher than that in a surrounding nutrient solution. The phosphorus concentration in the transpiration stream of shaded barley seedlings has been estimated to be about  $5 \times 10^{-4}$  molar whereas that of the nutrient solution around their roots was  $3 \times 10^{-6}$  molar<sup>1</sup>. Neither the mechanism of concentration nor its location is known. It is obvious, however, that an accurate knowledge of the distribution of ions within the root is essential to an understanding of the mechanisms of accumulation and translocation. Autoradiography of frozen tissue sections has been successful in the location of low molecular weight substances in cells and tissues<sup>2,3</sup>. This communication describes the use of this technique to locate phosphorus-32 in transverse sections of maize roots.

The method used was that described previously<sup>2</sup>, but it was modified to allow the results to be analysed with an orthodox microdensitometer. This method of analysis requires a denser photographic image than the more usual method of counting grains used to evaluate autoradiographs. High concentrations of radioactivity were therefore used. It was also essential that only the photographic image should appear in the final preparation. The tissue section would interfere with densitometry. The method of film development was modified to ensure that no fragment of plant tissue remained attached to the film after development. The absence of any histological detail superimposed on the autoradiograph made it necessary to stain and mount alternate sections for comparison with the autoradiographs.

Maize seeds, *Zea mays* (L), variety 'White Horse Tooth', were germinated on moist filter paper and grown for 6 days in an aerated solution of  $10^{-5}$  molar calcium sulphate at 25° C. The seedlings were transferred to a  $3 \times 10^{-6}$  molar solution of potassium phosphate which was labelled with 1 mc./l. of phosphorus-32 (carrier free orthophosphate). After 15 min the seedlings were removed, rinsed, blotted dry and the apical 0.75 cm was embedded in a 1 cm cube of fresh swine's liver. The block was frozen on a microtome object holder by immersing the metal base in isopentane cooled with liquid nitrogen. This method froze the block and root in about 20 sec. Transverse sections, 10 µ thick, were cut from the region 5 mm from the root tip, with a cryostat microtome at -20° C.

Cover slips were prepared for coating with Kodak AR.10 stripping film by soaking in a 1 per cent solution of R.B.S. 25 detergent, immersion for 1 h in a solution of 1 per cent gelatine, 0.05 per cent chrome alum ( $\text{Cr}_2(\text{SO}_4)_3 \cdot \text{K}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$ ), and drying in a stream of cool air. This careful preparation was essential if the film was to remain attached to the coverslip in the extreme conditions which are required during development to ensure the complete removal of the tissue section. The coverslips were coated with film, and the sections were transferred from the microtome knife to the emulsion, using the methods and conditions already described<sup>2</sup>. The coverslips bearing sections were placed 3 mm apart in plastic racks and left in light proof boxes at -20° C for exposure of the film. After a week boxes were removed from the deep freeze and the contents were allowed to reach room temperature before processing. The films were developed in Kodak D19b at 18° C, fixed in Johnson's 'Fixsol' at 22° C, and washed in distilled water at room temperature (17° C-24° C). These variations in temperature and the absence of any cytological fixation usually left no trace of any plant material on the film. The section following each one that was used to prepare an autoradiograph was picked from the microtome knife with a slide coated with albumin, fixed in 95 per cent alcohol, 5 per cent acetic acid, stained in Ehrlich's haematoxylin, and mounted ready for comparison with the autoradiographs.

The variation in optical density over the autoradiograph was measured using a microdensitometer, which was adjusted to measure continuously the optical density of a square, of side  $10\mu$ , as the specimen was moved in a straight line past the aperture. The instrument produced a plot of optical density against displacement along any selected  $10\mu$  wide strip across the autoradiograph. For the optical density of the photographic image to be proportional to the radioactivity of the specimen it was essential that the probability of "coincidence" is low ("coincidence" is the production of one observable silver grain by two or more disintegrations). In this investigation the optical density of fully exposed emulsion was compared with the maximum optical density observed in the autoradiograph; the results were discarded unless the former was at least three times as great as the latter<sup>4</sup>.

Fig. 1 shows a transverse section, cut 5 mm from the tip of a 6 day old maize root. The preservation of cell contents is excellent, but crushing and shattering of the material are a problem when plant organs are being cut. Section quality depends on careful control of temperature and this is facilitated by the provision of a means of direct measurement of temperatures of knife and tissue. These temperatures may be different from the temperature of the air in the cabinet after the microtome has been in use for 1 or 2 h. Fig. 2 shows an autoradiograph prepared from the section cut immediately before that shown in Fig. 1. Fig. 3 shows the change in optical density along a diameter of the autoradiograph.

Fig. 1. Transverse section of a young maize root. The section was  $10\mu$  thick and was cut 5 mm from the root tip. E, Epidermis; F, endodermis; P, phloem; X, xylem vessels; Y, xylem parenchyma; C, cortical cells.

Fig. 2. Autoradiograph of a section similar to that shown in Fig. 1.

Fig. 3. Microdensitometer trace showing the variation in optical density along the diameter  $\times-\times$  of the autoradiograph shown in Fig. 2. A, Epidermis; B, endodermis; C, xylem vessels; inset D, variation in optical density along a graticule which had etchings  $10\mu$  apart.

The high energy (1.7 MeV) of the electron emitted during decay of phosphorus-32 leads to considerable image spread, due to "crossfire"; that is when electrons which originate from one structure dissipate their energy in a part of the emulsion corresponding to another. Estimates of crossfire corrections applicable to phosphorus-32 autoradiographs<sup>4</sup> indicate that it is impossible to equate image density and concentration of phosphorus-32 in structures as small as the vessel elements in maize roots. The results of densitometry must therefore be regarded as qualitative. Nevertheless three observations are valid. (a) Phosphorus-32 is more concentrated in the vessel elements than it is in the surrounding phloem and parenchyma. (b) There is a gradient of concentration of phosphorus-32 across the root cortex, towards the endodermis and there is a point of inflexion in this midway between epidermis and endodermis. The detection of this illustrates the greater sensitivity of microdensitometry when compared with visual analysis of preparations or photographs. (c) There is an area of accumulation of phosphorus-32 which corresponds to the surface of the root, bacteria on that surface, or the epidermal cells.

The interpretation of single preparations must be cautious. It is unwise to regard optical density gradients in autoradiographs as evidence of gradients of activity in pathways of phosphorus movement without further information on the chemical form of the phosphorus-32 within the root, the turnover rates of the various species, and the volumes of the compartments through which it is moving, or in which it is accumulating.

I thank the Salters' Institute of Industrial Chemistry for the award of a fellowship.

### Peculiar Placenta in African Cucurbit, *Ruthalicia*

*Ruthalicia* (*Phyzedra* Hook. f.) has been established<sup>1</sup> out of two African species *Phyzedra longipes* Hook. f. and *P. eglandulosa* (Hook. f.) Hutch. and Dalz., and is considered a taxonomic synonym of *Coccinia* Wight and

Arn. which again is a taxonomic synonym of *Staphylosyce barteri* Hook. f. transferred to *Coccinia* by Keay<sup>2</sup>.

The species *Ruthalicia eglandulosa* (Hook. f.) Jeffrey is widely distributed all over Ghana. It is an extensive dioecious climber which has creamy yellow flowers with digital five-lobed leaves. The fruits when ripe have an attractive crimson colour with yellow patches. The ovules are arranged horizontally over the inner wall of the triplacentiferous unilocular ovary and are completely wrapped over in beaded fashion by a yellow succulent placental membrane. A second finely hyaline tissue covers the black and somewhat bluntly deltoid seeds.

Fig. 1. A, Fruit of *Ruthalicia eglandulosa* (x c. 0.65); B, cross-section of the same (x c. 0.65).

Fig. 2. A, Chain of seeds wrapped over by the placenta (x c. 0.9); B, a single seed, placenta removed (x c. 0.9).

The seeds are packed up serially in six rows bilaterally and attached to a parietal placental rod or axis and wrapped over by the cloth of placental membrane. The vertical placental axis is formed by the fusion of two contiguous vascular strands of the carpel margins. When slightly pressed, the placenta detaches itself from the vertical placental axis in the form of a perfect chain enclosing the seeds like a beaded necklace (Fig. 2A) and it spreads automatically when placed on a Petri dish filled with water. The succulent yellow placenta is partially dissolved into mucilaginous consistency when the fruit ripens and the contents are invariably eaten in the wild state by birds or other animals. Seldom is an intact ripe fruit found in nature. The empty shells of the fruits are often found hanging on the vine with pulp completely eaten away. When unripe the shell is hard and is green in colour with a few white stripes radially disposed at the

apical part. On keeping, the green area turns brilliantly crimson and the white stripes yellow within two weeks and the hard shell softens considerably. If not disturbed the fruit keeps well for over a month or more under room temperature. Morphology of this peculiar placenta is being investigated.

### Polymorphism in the Spider, *Theridion ovatum*

REFERENCE has often been made<sup>1-3</sup> to the colour varieties of *Theridion ovatum*. According to Locket and Millidge<sup>4</sup>, the abdomen may have one of three colour patterns: Clerk's *lineatum*, abdomen creamy white; Clerk's *redimitum*, abdomen with a pair of wide longitudinal carmine stripes; Clerk's *ovatum*, abdomen dorsally covered with carmine. Field observations confirm that these varieties are polymorphic, in accordance with the accepted definition<sup>5</sup> for genetic polymorphism.

Counts of the three varieties in the field indicate that populations are panmictic, and a computation of the type used to determine the frequency of MN blood groups<sup>6</sup> suggests that the colour varieties, *lineatum* and *ovatum*, are under the control of a single pair of alleles. The heterozygote, which shows incomplete dominance with respect to abdominal colour, is *redimitum*.

The following results are derived from counts by Nielsen<sup>2</sup> and Bristowe<sup>3</sup>. Nielsen made counts in two separate habitats, while Bristowe's figures represent the sum total of many counts. The frequencies of the three forms of spider are found to vary between populations, a point which is made by Bristowe. Separate and total counts provide independent material with which to test whether the observed data differ significantly from what is expected with the Hardy-Weinberg law.

Table 1. COMPARISON OF OBSERVED AND EXPECTED FREQUENCIES OF VARIETIES OF *Theridion ovatum*

Variety	No.	Percentages		
		Observed	Expected	$\chi^2$
<i>Lineatum</i>	55	55.0	51.8	1.98
<i>Redimitum</i>	34	34.0	40.4	1.01
<i>Ovatum</i>	10	10.0	7.8	0.62
Total 3.61, $P > 0.10$				
<i>Lineatum</i>	19	33.9	37.9	0.42
<i>Redimitum</i>	31	55.4	47.3	1.39
<i>Ovatum</i>	6	10.7	14.7	1.09
Total 2.90, $P > 0.20$				
<i>Lineatum</i>	2,714	64.24	63.7	0.004
<i>Redimitum</i>	1,316	31.15	32.2	0.034
<i>Ovatum</i>	195	4.16	4.0	0.001
Total 0.039, $P > 0.98$				

I thank D. W. Mackie (secretary of the British Spider Study Group) and G. Corris for their assistance in this work.

### Presence of *Haemoproteus* sp. in House Sparrows in England

ALTHOUGH there have been many records of *Haemoproteus* in the English sparrow (*Passer domesticus*) from America and Europe<sup>1-3</sup> there appears to be no published record of the parasite occurring in Britain.

Recent examinations of blood films taken from the peripheral blood of nineteen sparrows which had become trapped in experimental animal buildings at Weybridge showed two of the birds to be infected with *Haemoproteus*. One bird had a pure infection of *Haemoproteus*, the other a mixed infection of *Haemoproteus* and *Plasmodium relictum*. *P. relictum* was present in less than 1 per cent of the erythrocytes. Because of morphological differences between the two *Haemoproteus* parasites, those from the sparrow with the double infection were designated Type A, and those from the pure infection Type B.

In the blood parasitized by Type A, the parasitaemia was 0.69 per cent, calculated from 10,000 erythrocytes, most of the parasites being mature gametocytes similar in shape to those usually described (Fig. 1). With only a few exceptions there was only one parasite in each parasitized cell. Of the gametocytes 67 per cent were macrogametocytes and 33 per cent were microgametocytes. The microgametocytes in Type A showed a hyaline cytoplasm which stained pale blue or pinkish, with a dispersed nucleus containing fine chromatin granules. By comparison the cytoplasm of the macrogametocytes stained a much deeper blue. The nucleus was compact and contained a karyosome. The light brown pigment granules of the microgametocyte were generally aggregated into masses towards the poles, whereas those of the macrogametocyte were uniformly scattered throughout the parasite. Counts of the numbers of pigment granules showed that the

average number for microgametocytes was 9.14 (minimum 6, maximum 12), and for macrogametocytes 12 (minimum 9, maximum 15).

In the B type infection the parasitaemia was 10.06 per cent. Many cells contained two or three young gametocytes. There was a greater morphological difference between the mature gametocytes than in Type A. In particular the microgametocytes were larger and broader with their poles flat rather than rounded and some with finger-like edges. There was also slight displacement of the host cell nucleus in many of the parasitized cells. This was not observed with Type A.

Immature gametocytes were more predominant. Differential counts of mature gametocytes showed that 41 per cent were macrogametocytes and 59 per cent microgametocytes.

Pigment granules were yellow in colour, and counts showed the average number for microgametocytes to be 10.6 (minimum 6, maximum 17) and for macrogametocytes 13.12 (minimum 9, maximum 19). Although the range between minimum and maximum numbers is greater in Type B than in Type A, it is unlikely that this difference is significant.

The absence of tissue stages from these infections, and the lack of sufficient visual descriptions from existing records, makes it difficult to enable an accurate comparison to be made with specifically recorded species of the parasite.

It is not possible to be sure whether the infections in the two birds are of different species of *Haemoproteus* or whether they merely represent different morphological phases. Different species of the parasite may possibly infect the same species of bird<sup>4</sup>.

It is hoped that this record of *Haemoproteus* will stimulate further examinations of *Passer domesticus* throughout the British Isles, and that the vector will eventually be identified.

### Breeding Frequency in the Albatrosses *Diomedea melanophris* and *D. chrysostoma*

It is now generally accepted that the two great albatrosses *D. exulans* and *D. epomophora* take about twelve months to rear their young, and if successful breed only in alternate years<sup>1-4</sup>, but the breeding cycles of the smaller species are not so prolonged and there has been less reason to suppose that annual breeding is not the rule. Recent studies at Bird Island, South Georgia (54° 00' S., 38° 02' W.) (ref. 5), however, indicate that although the black-browed albatross *D. melanophris* breeds annually, the grey-headed albatross *D. chrysostoma* breeds less frequently.

The two species are closely related, and both belong to that group of albatrosses known as mollymauks. There is no significant difference in size or body weight between adults, and although the head plumage and bill markings are strikingly different, the similarity of their habits and behaviour on the breeding grounds has led to the observation that remarks on the nesting of one species apply equally to the other<sup>1</sup>. In fact, although they are not easy to demonstrate, differences are apparent in breeding biology, oceanic distribution<sup>6</sup> and feeding<sup>7</sup>.

Both species breed in large dense colonies on steep slopes of rock and tussock grass *Poa flabellata* at the tops of sea cliffs. Generally they are segregated, but colonies of one species sometimes merge into those of the other, and it is not uncommon to find nests of *D. melanophris* in the midst of *D. chrysostoma* colonies, although the reverse does not seem to occur<sup>8</sup>. The breeding cycle of *D. chrysostoma* is about a month longer than that of *D. melanophris*. *D. chrysostoma* first return to the island on about September 15, about ten days before *D. melanophris*, and the peak departure of *D. chrysostoma* fledglings, May 15, is about three weeks later than for *D. melanophris*. Most intact pairs of *D. melanophris* use the same nest each season; we have records of 38 pairs using the same nests for two consecutive seasons and of five pairs for three seasons.

Between January and March 1963, 97 *D. melanophris* adults were banded at 50 nests where they were feeding nestlings. The following breeding season 38 (76 per cent) of these marked pairs are known to have laid eggs in the same nests. At the other twelve nests, one of the original pair was seen in nine, and in three neither of the birds was observed. None of the missing birds bred elsewhere in the colony. In any representative sample, mortality alone will remove a proportion of the breeding population each year and thereby interrupt breeding at some nests. In *D. melanophris* the adult mortality calculated from the return of 138 marked birds over two years was 6.7 per cent per annum. On this reckoning about seven of the original 50 pairs probably failed to produce eggs in the second season owing to the death of one bird, the probability of one bird of a pair dying being greater than that of both birds dying in the same year. We have no record of the remaining five pairs (10 per cent) which failed to breed in the second season.

In the spring of 1963-64 winter conditions persisted later than usual. Because of ice and snow, both species had difficulty building nests and a large number of eggs were lost. Birds that lose eggs soon after laying frequently do not stay in the colony, and since observations generally lasted only 2-3 h each day it is reasonable to suppose that some marked birds were not seen. In these circumstances we consider a 10 per cent discrepancy to be acceptable, and the data sufficient evidence of annual breeding in *D. melanophris*.

Between March 22 and April 3, 1963, one hundred *D. chrysostoma* at 88 nests were marked while feeding well grown fledglings, most of whom departed in early May. The following season, in spite of a very close watch, only 19 of these birds were observed in the colony; none of them laid eggs and all had departed by the end of the egg laying period. Bad weather conditions prevented field workers visiting Bird Island in 1964-65, and confirmation of breeding in the third season is therefore not available. There is evidence, however, from five other nests that pairs which lose eggs or very young chicks do in fact return and breed again the next year.

The possibility of intermittent breeding in the Fulmar *Fulmarus glacialis* was pointed out by Wynne-Edwards in 1939<sup>9</sup>. A more recent study of the Laysan albatross *D. immutabilis* by Rice and Kenyon<sup>10</sup> reported 63-87 per cent of birds breeding again after one year, and led to speculation about the possibility of "... a decreasing tendency to nest the following year with an increase in the length of the portion of the breeding cycle that is successfully completed. . .". The 10 per cent of *D. melanophris* pairs unaccounted for at Bird Island could indicate similar behaviour, but since we cannot be absolutely sure that some birds which lost eggs were not missed, we are bound to adopt the simplest hypothesis consistent with the error, that is, annual breeding. Similarly, it is clear from our evidence that *D. chrysostoma* does not breed annually; and from what we know of the reproductive cycles of the great albatrosses biennial breeding might be inferred, were it not for the marked

difference between the lengths of breeding cycle in the great albatrosses and *D. chrysostoma*. Wandering albatrosses, which are still feeding advanced fledglings when other birds are arriving in full nuptial condition, would have no post-nuptial season unless one breeding season were missed. Circumstances are quite different for *D. chrysostoma*; at least four months intervene between the departure of fledglings and the arrival of the next season's breeding adults, but for some reason this is not sufficient to enable *D. chrysostoma* to breed each year. In contrast, *D. melanophris* breeds annually although absent from the breeding grounds for only five months each winter.

Among the five species of mollymauk, Buller's albatross *D. bulleri* and the yellow-nosed albatross *D. chlororhynchos* closely resemble *D. chrysostoma*. There are no data available to indicate whether there is any similarity in breeding frequency, but Rowan<sup>11</sup> makes a significant observation in her paper on *D. chlororhynchos*: "... Three marked nests at Sandy Point, Tristan da Cunha, which were all in use during the summer of 1949-50 were left untenanted the following spring although the numbers of nesting birds in the locality had definitely increased . . .", a hint at least that breeding may not have occurred each year.

The discussions of Lack<sup>12</sup>, Wynne-Edwards<sup>13</sup> and Ashmole<sup>14</sup> have all drawn attention to relevance of breeding frequencies to population control in Procellariiformes, and while it is impossible at the moment to suggest mechanisms behind different frequencies in *D. melanophris* and *D. chrysostoma* it is evident that they reflect profound differences in the niches that these species occupy in the oceanic environment. This work was undertaken while the authors were in receipt of grants from the U.S. National Science Foundation.

### Effect of Two Diuretic Drugs on Liquid Consumption and Free Choice of Alcohol in Albino Rats

EARLIER experiments in our laboratories<sup>1</sup> with animals on a free choice between water and an ethyl alcohol solution have indicated that the amount of alcohol consumed relative to the total fluid intake, the so-called alcohol preference, is influenced by the water requirement of the animal and by its ability to metabolize alcohol. This

Table 1. ALCOHOL AND WATER CONSUMPTION BEFORE AND DURING TREATMENT WITH DIURETIC AGENTS

		Alcohol preference	Total liquids (ml.)/100 g body weight/day	Amount of alcohol consumed calculated as absolute alcohol/100 g body weight/day	Food (g)/100 g body weight/day
Group 1	Normal free choice period	51.1 ± 18.4	8.50 ± 2.8	0.44 ± 0.22	4.52 ± 1.5
	Statistical significance	0.01 < P < 0.02	0.001 < P < 0.005	P < 0.5	P < 0.5
	'Dichlotride' period	36.3 ± 12.7	11.73 ± 2.0	0.43 ± 0.18	4.49 ± 1.5
Group 2	Normal free choice period	64.8 ± 19.1	8.89 ± 1.5	0.57 ± 0.23	4.89 ± 0.4
	Statistical significance	0.001 < P < 0.005	P < 0.001	P < 0.5	P < 0.5
	'Hygroton' period	38.9 ± 14.5	12.79 ± 2.6	0.51 ± 0.21	4.83 ± 0.9

means that the absolute amount of alcohol per unit of body weight remains unchanged when the concentration of the alcohol solution is changed. On the other hand, an increasing water requirement may change the calculated alcohol preference, even if the absolute amount of alcohol remains unchanged.

In this experiment changes in liquid consumption were induced by two different diuretic drugs and their effect on the free choice of alcohol was investigated. Twenty white Wistar male rats were used in the experiment. They were 4 months old at the start and weighed  $298.6 \pm 35.5$  g. The rats were divided into two equal groups. They were placed in individual cages and freely offered tap water, 10 per cent (v/v) alcohol solution and our standard laboratory food. This normal free choice period lasted 14 days. Then the first group received in its food 30 mg/kg of hydrochlorothiazide 'Dichlotride', which is the 3,4-dihydro derivative of chlorothiazide (6-chloro-7-sulphamyl-1,2,4-benzothiadiazine-1,1-dioxide). The second group was given 40 mg/kg of 'Hygroton', 1-oxo-3-(3-sulphamyl-4-chlorophenyl)-3-hydroxy-isindolinum. The choice of liquid consumed during the drug period was recorded for 10 days.

Table 1 shows that liquid consumption during the drug period in the animals on 'Dichlotride' was 38 per cent, and in those on 'Hygroton' 44 per cent, above normal. In both groups the increase was statistically significant. As the absolute amount of alcohol per unit of body weight remained unchanged, the relative amount of alcohol decreased. This change is shown by a statistically significant decrease in the percentage of preference. There were no individual exceptions to this rule. Even those rats in which the preference percentage was originally low and absolute alcohol consumption minimal showed a decrease in percentage intake and did not change the amount of alcohol consumed. No adverse side-effects of the drugs were recorded. Food consumption remained unchanged.

From the results of this experiment it seems evident that an alcohol solution cannot replace water in a free choice situation when the alcohol concentration is high. Each individual has its fixed level of alcohol intake, which it does not surpass. The reaction to different concentrations is partly determined by this level. The observed increase in alcohol preference with increasing age<sup>2,3</sup> is probably caused by the same thing, at least in young rats. The total fluid intake decreases with age, and so the proportion of alcohol increases although the absolute alcohol consumption remains unchanged. In free choice experiments on alcohol, the absolute consumption seems to be more significant for the interpretation of the results than the relative alcohol preference.

I thank P. Mäenpää for his stimulating discussion and Miss M. Gustafsson for her assistance in the laboratory work.

## APPLIED SCIENCE

### Strain Rate Effects on Low Endurance Fatigue

FATIGUE investigations in which the strain is high and the endurance low have been prominent in the past decade. Usually these have utilized testing machines that have previously been used for conventional fatigue investigations, that is for lives greater than 100,000 cycles. In consequence series of high strain tests have been performed with a constant frequency of cycling.

Using the notation where  $\Delta\epsilon$  is the total strain range,  $\Delta\epsilon_e$  the elastic strain range,  $\Delta\epsilon_p$  the plastic strain range,  $\Delta\theta_p$  the plastic torsional twist range,  $\dot{\epsilon}$  the straining rate,  $N_f$  the number of cycles to failure at a given strain range,  $n$  the number of cycles completed at a point in the fatigue life at a given strain range,  $t$  the time per cycle, and  $f$  the frequency of cycling, it follows that

$$t = 2\Delta\epsilon/\dot{\epsilon} \quad (1)$$

and

$$\Delta\epsilon = \Delta\epsilon_e + \Delta\epsilon_p \quad (2)$$

From equation (1) it can be seen that in the strain range for fatigue in which the endurance is low and which involves an appreciable amount of plastic deformation, a constant frequency of testing will necessarily cause a wide variation in straining rates because

$$2\Delta\epsilon.f = \dot{\epsilon} \quad (3)$$

For example, with data from fatigue tests in which the strain is high and the endurance low, I find that the ratio of the maximum to the minimum straining rate would have been 10:1 if tests had been performed at a constant frequency. It seems necessary therefore that, in the range of low endurance, fatigue tests should be carried out at constant straining rates if a better basic understanding of the phenomenon is to be achieved. Frequency, after all, is only the number of cycles performed within an arbitrary time interval and should not be thought of as an important parameter.

The argument for using constant straining rate machines can be furthered by considering the Miner-Palmgren linear cumulative damage law

$$\Sigma n/N_f = 1 \quad (4)$$

With reference to fatigue data that are usually presented in the now well established Coffin-Manson relationship form

$$\Delta\epsilon_p.N_f^a = \text{constant} \quad (5)$$

Fig. 1 shows results of torsional fatigue investigations in which the endurance is low carried out at constant straining rates on a 2.5 nickel-chromium-molybdenum steel ( $E_n$  25). The upper curve applies to the maximum straining rate investigated while the lower curve was deduced by extrapolation from a number of tests at various straining rates. From these results it appears that there exists a minimum endurance curve corresponding to a zero straining rate and a maximum endurance curve corresponding to a critical level of straining rate beyond which there is no strain rate effect on the endurance characteristics. Increasing the straining rate between

these limits causes a significant increase in the fatigue endurance at high strain values. The result is not unexpected when it is compared with recent results obtained by increasing the frequency of cycling<sup>1</sup>; however, the importance of such results can best be seen by investigating Fig. 2 and the Miner-Palmgren law.

Let  $a-a$  and  $b-b$  represent endurance curves for a material strained at low and high rates, respectively. Thus a curve similar to  $c-c$  will represent endurances for a constant frequency of cycling. If a two step investigation into cumulative damage is studied between levels 1 and 2 and if the low level strain range is applied initially to account for 50 per cent life, then this will correspond to distance  $2-4a'$ . When the second step and higher level of strain are applied, the 50 per cent proportion of life already used is equal to the distance  $1-3a$  at the same straining rate. If the second half of the test is carried out at the same frequency as the first half, however, it can be assumed that 50 per cent damage is equated to point  $3b$ , not  $3a$ , and an apparently extended life results. The reverse applies if the higher level strain is applied initially and the summation  $\Sigma n/N_f$  is less than 1 as a result of the non-coincident points  $4a'$  and  $4b'$ .

This argument can also be used to invalidate the hypothesis that endurance to high strain fatigue is determined by a critical level of accumulated plastic strain energy. Recent work<sup>2</sup> on this subject tends to disprove this hypothesis, but if the results are referred to constant straining rates then the curves of a plot of the logarithm of the total plastic strain energy to failure against the logarithm of the number of cycles to failure would have slopes greater than those recorded and so be further removed from a constant critical level of accumulated plastic strain energy.

In the discussion of Mackenzie and Benham's paper<sup>2</sup> cumulative damage summation terms are presented for

Fig. 1. Comparison of  $\log \Delta\theta_p - \log N_f$  relationships for two straining rates.

Fig. 2. Effect of strain rate on cumulative damage.

low endurance fatigue, and while the two levels of total plastic diametral strain ranges are in a ratio no greater than 1:2.25, high to low level 2 step test summation terms are always less than 1 and from low to high levels the summation is always greater than one. This is typical of the deviations from the Miner-Palmgren law recorded by numerous investigators who have used constant frequency of cycling machines.

### Reciprocating-jet Pump

A PUMP designed to operate with corrosive liquids at extremely high temperatures will usually be constructed from refractory oxides and hence, if possible, must not rely on solid moving parts such as valves, pistons and rotors. A simple method of achieving this is to make use of some non-reciprocal hydrodynamic effect.

A conventional jet pump is valveless and uses a fluid jet separately pumped into a suitably shaped main pipe, which carries the fluid to be pumped. The main body of fluid is propelled along this pipe by a momentum transfer and mixing process. The injected fluid must, however, be suitable for pumping by conventional means, be compatible with the pumped fluid, and be acceptable as a diluent. At high temperatures these conditions will usually eliminate all fluid combinations apart from a gas or vapour to pump a liquid, and vice versa. Unfortunately there is then a large mismatch in density which causes considerable energy loss during momentum mixing.

Another possibility is to extract from the main pipe an appropriate amount of the fluid to be pumped, in readiness for re-injection. During this extraction or "suck" stroke the fluid mass removed at a sink or jet orifice contains very little momentum before entering the orifice. During the injection or "blow" stroke, however, the jet orifice acts as a source of momentum directed as desired. This is then coupled to the surrounding fluid in the main pipe, with an unavoidable but not excessive energy loss. Over a complete "suck-blow" cycle a net forward thrust is created, which may be used to generate a pressure rise or a velocity increase in the main body of fluid, depending on the shape chosen for the main pipe.

The non-reciprocal action of an alternating jet depends on the fact that the flow pattern for a steady suck stroke is fundamentally different from that for a steady blow stroke. This may be seen in the streak photograph (Fig. 1), which was taken in a two dimensional water tank using polystyrene beads as markers. The left-hand jet is sucking and the right-hand blowing. During the suck stroke irrotational potential flow occurs with a convergent "scalar" flow pattern in which  $\text{curl } \mathbf{v} = 0$ , where  $\mathbf{v}$  is the fluid velocity. At the start of the blow stroke a divergent flow pattern occurs momentarily, but because of viscous forces in the boundary layers the liquid cannot sustain the large velocity gradients around the edges of the jet orifice, and a rotational motion is started. The transient potential flow pattern therefore breaks down as inertial forces take over control. Ring vortices are generated around the periphery of the jet orifice and are shed downstream, so that in the steady state there is a gradual erosion of the jet associated with a widening of its influence as ejected fluid enters a turbulent mixing region. A steady thrust is the ultimate result. The flow pattern of the blow stroke might be regarded as a "vector" pattern in which  $\text{curl } \mathbf{v} \neq 0$ .

The problem of pumping a steady stream of fluid has now been transformed to that of cycling fluid through a

jet orifice. In a severe environment the latter problem is much more simple to solve, for example, by use of a vertically reciprocating gas-liquid interface stabilized by gravity. This forms a piston in a chamber coupled to the jet orifice by means of a suitable diffuser or nozzle. In the case of a pump for liquids, the gas pressure above the liquid surface may be cyclically varied by means of a reciprocating mechanical piston or by a valve-controlled supply of compressed gas, so as to blow and suck alternately through the jet orifice. Two alternative methods of varying the gas pressure are based on the two-stroke internal-combustion engine and the steam engine. In the latter method, it might be advantageous to use the vapour of the liquid being pumped. A more speculative technique, which is particularly suited to the pumping of some very hot liquids, would be to inject water on to or below the surface of the hot liquid within the piston chamber. This water would be converted immediately to steam, forcing liquid out through the jet. The piston chamber could then be opened to a condenser for the suck stroke. The pumping power would be derived at the expense of a small drop in liquid temperature.

Fig. 1. Reciprocating-jet pump.

Experiments have been carried out on the pumping of water in various configurations of pump, using up to four jets. Particular attention is now being given to "twin-jet" forms of the pump in which each stage comprises two jets in anti-phase directed at a venturi orifice. The streak photograph (Fig. 1) shows that there is little interference between the two jets. An experimental pump, with angled jets attached to the main pipe like the branches of a tree, has been constructed from drilled refractory bricks and will be tested with molten salts at 1,500° K.

A simple theory, based on separate consideration of steady state blowing and steady state sucking, has been found to give reasonable agreement with the results. The pump head ( $h_p$ ) in m or ft. of the liquid pumped is given for equal periods of blow and suck by:

$$h_p = [n\alpha\bar{v}_j^2/2g][1 - 2(v_p/\bar{v}_j) - \alpha/2]$$

where  $n$  is the total number of jets;  $\alpha$  is the ratio of the area of each jet to that of the pipe;  $\bar{v}_j$  is the mean jet velocity;  $\bar{v}_j^2$  is the mean square velocity;  $v_p$  is the pipe velocity just before mixing, and  $g$  is the acceleration due to gravity. It is assumed that when more than one jet is involved, the jet velocities are suitably phased to give zero net addition of fluid at any given moment.

At high frequencies, or short wavelengths, as defined by the ratio of pipe velocity to frequency, the steady state treatment is likely to be less accurate. In order to allow for transients during switch-over, a more sophisticated approach is required which involves considering the ring vortex streets.

The main drawback to the reciprocating-jet pump is that the pumping efficiency is unlikely to exceed 38 per cent at best, and a more realistic figure would probably be half this. Nevertheless there are many applications where efficiency is less important than some other consideration such as the absence of solid moving parts. The reciprocating-jet pump should be considered for application to the pumping of the following materials: molten metals, slags, glasses and salts, where high temperatures and corrosion are a problem; blood, where contamination must be avoided; solid suspensions, where blockage and erosion can occur, and liquid gases such as helium at low temperatures.

My thanks are due to Mr. J. R. Stutely for many useful ideas in development of the pump and also to Mr. R. C. Kell for valuable comments on the manuscript.

## GENERAL

### Entropy and Information in the Universe

POPPER<sup>1</sup> denies the cosmic significance of the principle of increase of entropy, stating that "the entropy in almost all known regions (of sufficient size) of our universe either remains constant or decreases, although energy is dissipated (by escaping from the system in question)". This statement seems in error when we assume the "cosmological principle" that the distribution of energy and matter in the universe on a large scale is uniform in space. Consider a volume of space so great that it contains several thousand galaxies. Through the limits of this system there is—on the large scale—no flow of energy or entropy. In the interior of the system the total entropy at least does not decrease; it increases (among other things) to the extent that the radiation emitted by the stars is transformed (by interaction with matter, for example) into black-body radiation uniformly distributed throughout the volume.

Popper appears to assume that the total entropy of an energy conserving expanding universe should decrease because of the cooling caused by the expansion. This assumption contradicts the well established calculations of R. C. Tolman, made on the basis of general relativity<sup>2</sup>. Tolman shows that the total entropy of such a universe either remains constant or (in general) increases.

Popper criticizes the idea that a living organism would be "fed on negentropy by its environment", for "during the incubation of birds' eggs, entropy rather than negentropy is supplied to them, though they are in a period of increasing organization; and . . . when an organism dies of cold . . . its entropy certainly decreases". This criticism seems to be based on a misunderstanding of what is meant by "feeding on negentropy". To clarify things, let us consider a watchmaker putting the separate parts of a watch together to make a functioning mechanism. By

doing so the watchmaker "puts information into the watch", that is, the information of how the single parts are to be combined. The information contained in the watch can be measured in bits, as has been shown by Brillouin and others<sup>3</sup>. Whenever a mechanism containing an information of  $n$  bits is built, the thermodynamic entropy of that mechanism or its environment must increase by the amount of at least  $kn \log 2$  where  $k$  is Boltzmann's constant. The quantity  $kn \log 2$  is, in fact, the information measured not in bits but in caloric units (cal/grad). So we may consider the information to be "structural negentropy" contained in the mechanism, and state the principle: whenever structural negentropy is produced, the thermodynamic entropy must increase by at least the same amount. This principle is proved in the case of structural negentropy produced by man, but very probably it also holds for structural negentropy produced by nature in an organism. The increase of thermodynamic entropy may be found in the evolving organism itself; so the birds' eggs quoted by Popper do not constitute a rebuttal. The death of an organism means a loss of its structural negentropy, but not necessarily an increase of its thermodynamic entropy.

*Note added in proof.* When the space as a whole is considered as expanding, the part of space of which we spoke in the discussion of the entropy question must, of course, be considered as correspondingly expanding, too (see Tolman's book).

### Time's Arrow and Feeding on Negentropy

My article, "Time's Arrow and Entropy"<sup>1</sup>, has produced so far only one voice of dissent, Professor Büchel's letter<sup>2</sup>. This letter consists of three paragraphs, to which I shall reply in order.

(1) I cannot find any argument in Professor Büchel's first paragraph which is even an attempt to come to grips with my arguments. Professor Büchel writes: "Consider a volume of space so great that it contains several thousand galaxies. Through the limits of this system there is—on the large scale—no flow of energy or entropy". This simply repeats the current view, which I criticized, without making any attempt to counter my arguments; for I quoted arguments to show that there always is a flow of energy in the form of radiation, and, if we assume an expanding Universe, also of matter, from any "well-defined geometrical volume" which is sufficiently large.

(2) In his second paragraph, Professor Büchel speculates on what I "seem to assume"; however, I did not assume that "the total entropy of an energy conserving expanding universe should decrease because of the cooling caused by the expansion". Rather, I tried to explain the fact that "[in almost all sufficiently large systems [that is, spatial regions] known to us, entropy production seems to be equalled, or even exceeded, by entropy loss through heat radiation", supporting this by "the conjecture that every entropy producing region is open towards some large (perhaps infinite) sinks of energy"<sup>3</sup>.

I stated explicitly that these considerations would not apply if we assume "a finite and non-expanding universe with non-zero energy density"; or, to put it more precisely, my arguments would not apply, according to Einstein<sup>4</sup>, to a closed universe which expands, if at all, to a temporary maximum, and then contracts; that is,

to a universe with positive spatial curvature, or to an Einstein universe the average mass density  $\rho$  of which exceeds  $3H^2/\kappa$ , where  $\kappa$  is Einstein's gravitational constant and  $H$  is Hubble's expansion constant. (Although Einstein sometimes showed support for such a universe, he was, of course, perfectly clear that this view involved very great difficulties<sup>4</sup>; moreover, he regarded the conjecture  $\rho > 3H^2/\kappa$  as untestable, and the opposite conjecture as testable or refutable<sup>5</sup>, which might make it preferable to some.) I did, therefore, admit that there might be relativistic universes with increasing entropy; but I tried to direct attention to the fact that we have reason to believe that there are others also, since every spatial region known to us, however large, loses heat, and thereby entropy.

(3) In the last paragraph of Professor Büchel's letter he refers to the last paragraph of my article, in which I criticized Schrödinger's suggestion<sup>6</sup> that organisms characteristically "feed on negentropy". Obviously, all heat engines "feed on negentropy" in some sense, because their intake contains less entropy than their total output; in fact, they are producers of entropy. Thus, there does not seem to be anything here which is characteristic of organisms. On the contrary, it seems that at least some organisms are extremely efficient and produce less entropy than most heat engines; they "feed entropy" to a lesser extent than non-organisms.

Professor Büchel claims that my criticism is based on a misunderstanding of the passage criticized, and that the passage should be interpreted in the sense of information theory. First, Schrödinger's book was published four years before Shannon's paper and even longer before "Information Theory" in the sense of "Brillouin and others", to whom Professor Büchel appeals. Second, all that Professor Büchel says about information theory and "structural entropy" is now well known (though neither "proved" nor necessarily accepted by all critics of the theory). And third, Professor Büchel again fails to counter my arguments. These are in two parts: (1) that in saying that organisms feed on negentropy, Schrödinger fails to say anything that distinguishes organisms from heat engines; and (2) that if, to use Professor Büchel's words, "the increase of thermodynamic entropy may be found in the evolutionary organism itself" (which simply means that the organism is an entropy producer), it is particularly interesting and strange that while birds' eggs appear to produce structural negentropy by increasing their structural organization, they are, as far as we know, "fed", in Schrödinger's sense, exclusively on heat (that is, on entropy). Professor Büchel does not attempt to explain why this does "not constitute a counter example" to Schrödinger's views.

Yet it would seem to force us, if we accept the usual views on entropy, to assume that all the negentropy needed by the developing bird was contained in the egg and spermatozoon, in the form of information. Though this may be so, it obviously speaks against Schrödinger's remark on the need of organisms to feed on negentropy.

I feel I should add in conclusion that I always was, and still am, a great admirer of Schrödinger; but I know that he would have abhorred the idea that anybody should be prevented by admiration or friendship from criticizing him.

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.20 p.m.—Dr. J. W. Mullin: "Crystallization—Art, Science and Technology".\*

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. T. L. Altbuler and Mr. J. W. Christian: "The Mechanical Properties of Pure Iron, Tested in Compression over the Temperature Range 2 to 293°K". Mr. J. Harding: "The Yield and Fracture Behaviour of High-Purity Iron Single Crystals at High Rates of Strain".

ROYAL INSTITUTION OF NAVAL ARCHITECTS (in the Weir Lecture Hall 10 Upper Belgrave Street, London, S.W.1), at 5 p.m.—Dr. R. L. Townsin: "The Frictional and Pressure Resistance of Two Lucy Ashton Geosims". Mr. A. Emerson: "The Calculation of Ship Resistance; Application of Guillotons' Method".

UNIVERSITY OF LONDON (at Guy's Hospital Medical School, London Bridge, London, S.E.1), at 5 p.m.—Prof. R. Amprino (Bari): "Histophysiology of Bone".\*

UNIVERSITY OF LONDON (at the London School of Economics and Political Science, Houghton Street, London, W.C.2), at 5 p.m.—Prof. Maurice Freedman: "Rites and Duties".\*

ASSOCIATION FOR SCIENCE EDUCATION (at the Institute of Education, Malet Street, London, W.C.1), at 5.30 p.m.—Mr. F. C. Brown and Mr. R. C. Champeney: "Electrons".

INSTITUTE OF PETROLEUM, ECONOMICS AND OPERATIONS GROUP (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. W. J. Newby: "Operations Research".

INSTITUTION OF CIVIL ENGINEERS, TRANSPORTATION ENGINEERING GROUP (at Great George Street, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Shopping Centres—Traffic and Economic Aspects" introduced by Mr. H. D. Peake.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.1), at 5.30 p.m.—Mr. D. Gignoux and Mr. J. Lazar: "Ion Propulsion".

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. G. B. Ansell: "The Metabolism of Brain Phospholipids". (Fifth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

UNIVERSITY OF LONDON (at the Institute of Laryngology and Otolaryngology, Royal National Throat, Nose and Ear Hospital, Gray's Inn Road, London, W.C.1), at 5.30 p.m.—Prof. G. J. Cunningham: "On Cancer".\*

SOCIETY FOR ANALYTICAL CHEMISTRY, SPECIAL TECHNIQUES GROUP (Joint meeting with the Polarographic Society, in the Chemistry Department, Imperial College, London, S.W.7), at 6.30 p.m.—Dr. A. B. Hart: "Fuel Cells".

## Thursday, January 26—Friday, January 27

CHALLENGER SOCIETY and REPRESENTATIVES FROM THE MARINE LABORATORIES (Natural Environment Research Council Scheme) (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 10 a.m. daily—Papers on Climatology and Geology; Fisheries; Biology; Instrumentation and Physical Oceanography.

## Friday, January 27

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Prof. G. Porter, F.R.S.: Introductory Lecture.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 6.30 p.m.—Discussion meeting on "Use of Electric Optic Effect for Light Modulation" opened by Mr. J. M. Ley.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. S. G. Hooker, C.B.E., F.R.S.: "The World of the Jet Engine Designer".

## Saturday, January 28

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Andrew Strathern: "A People of the New Guinea Highlands and their Mythology of Wealth".\*

## Monday, January 30

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "Ion Implantation" opened by Dr. J. Dearneley and Mr. L. Large.

UNIVERSITY OF LONDON (at Queen Elizabeth College, Campden Hill Road, London, W.8), at 5.30 p.m.—Prof. S. J. Pitt: "The Cultivation of Microbes and Cells" (Inaugural Lecture).\*

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Sir Gordon Sutherland, F.R.S.: "Science" (third of four Cantor Lectures on "Some Aspects of the U.S.A. Today").

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN MATHEMATICS—The Secretary of the Council, Girton College, Cambridge (February 1).

RESEARCH ASSISTANT to collaborate with other Imperial College physicists in a group working at CERN with a large magnet spark chamber, and to be resident principally in Geneva—Prof. C. C. Butler, F.R.S., Physics Department, Imperial College of Science and Technology, London, S.W.7 (February 1).

LABORATORY SUPERINTENDENT (with technical and administrative ability) IN THE SCHOOL OF BIOLOGICAL SCIENCES to be responsible for the organization and general technical services in the School—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR 88C (February 4).

CHAIR OF APPLIED MATHEMATICS at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 6).

LECTURER or ASSISTANT LECTURER IN THE HISTORY AND PHILOSOPHY OF SCIENCE—The Registrar, The University, Leeds, 2 (February 6).

CHAIR OF TELECOMMUNICATION SYSTEMS WITHIN THE DEPARTMENT OF ELECTRICAL ENGINEERING SCIENCE—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (February 7).

LECTURER IN STATISTICS—The Registrar, University of Kent at Canterbury, Canterbury, Kent, quoting Ref. A/32 (February 8).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF APPLIED MATHEMATICS—The Registrar, The University, Liverpool, quoting Ref. 312 (February 9).

LECTURER or ASSISTANT LECTURER IN MORAL PHILOSOPHY—The Secretary of the University Court, The University, Glasgow (February 10).

LECTURERS or ASSISTANT LECTURERS IN STATISTICS—The Acting Registrar, University College of Wales, Aberystwyth (February 10).

ASSISTANT LECTURER or LECTURER (with a medical qualification and preferably a dental qualification) in ORAL PATHOLOGY—The Registrar, The University, Sheffield (February 11).

LECTURER (preferably with a special interest in some aspect of electronics, for example microwaves or electromagnetic theory, together with some relevant research experience) in the DEPARTMENT OF ELECTRONIC AND ELECTRICAL ENGINEERING—The Registrar, The University, Sheffield (February 11).

SENIOR LECTURER and a LECTURER IN METALLURGY—The Registrar, The University, Sheffield (February 11).

ASSISTANT LECTURER or LECTURER (with special interests in the field of climatology and meteorology) IN GEOGRAPHY—The Acting Registrar, University College of Wales, Aberystwyth (February 13).

LECTURER (with a good honours degree in science or technology, and preferably research experience in building or civil engineering materials research) IN BUILDING SCIENCE—The Registrar, The University, Sheffield (February 13).

LECTURER or ASSISTANT LECTURER in (a) PHYSICAL GEOGRAPHY and in (b) ECONOMIC GEOGRAPHY at the University of the West Indies, Jamaica—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 16).

LECTURER or ASSISTANT LECTURER (with an honours degree in pharmacology, physiology or pharmacy, and for the lecturer a higher degree or research experience is desirable) IN PHARMACOLOGY—The Clerk to the Council, School of Pharmacy, University of London, 29/39 Brunswick Square, London, W.C.1 (February 17).

SECOND CHAIR IN THE DEPARTMENT OF ENGINEERING—The Registrar, The University, Leicester (February 18).

SECOND CHAIR IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, The University, Newcastle upon Tyne 1 (February 18).

HAYWARD RESEARCH FELLOW (medically qualified candidate) in the DEPARTMENT OF EXPERIMENTAL OPHTHALMOLOGY to undertake research on the early diagnosis of glaucoma—The Secretary, Institute of Ophthalmology (University of London), Judd Street, London, W.C.1 (February 20).

SENIOR LECTURERS or LECTURERS in MATHEMATICS at the University of Ibadan, Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 21).

PROFESSOR OF AGRICULTURAL EXTENSION at the University of the West Indies, Trinidad—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 22).

UNIVERSITY LECTURER (prepared to carry out research, supervise research students and co-operate in the teaching of one or more of the following fields: sedimentology, stratigraphy, geomorphology) IN GEOLOGY—The Secretary of Faculties, University Registry, Oxford (February 23).

ASSOCIATE PROFESSOR, SENIOR LECTURER or LECTURER GRADE I in the Division of Microbiology, Department of Pathology and Microbiology, University of Lagos—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 24).

ASSISTANT LECTURER IN PLANT PATHOLOGY—The Acting Registrar, University College of Wales, Aberystwyth (February 25).

CHAIR OF ANTHROPOLOGY and SOCIOLOGY at Monash University, Melbourne—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; or the Academic Registrar, Monash University, Clayton, Victoria, Australia (Australia and London, March 1).

LECTURER IN GENERAL PHYSIOLOGY in the School of Biology—The Registrar, The University, Leicester (March 1).

LECTURER IN PHILOSOPHY at Fourah Bay College, The University College of Sierra Leone—The Inter-University Council, 33 Bedford Place, London, W.C.1 (March 1).

PROFESSOR OF ZOOLOGY and CHAIRMAN OF THE DEPARTMENT OF ZOOLOGY AND COMPARATIVE PHYSIOLOGY, Monash University, Victoria, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 1).

DEPUTY HEAD OF THE MATHEMATICS DEPARTMENT to teach mathematics and statistics to scholarship level—The Headmaster, Monmouth School, Monmouth.

GOLDSMITHS' FELLOW (graduate, normally under 30 years of age, with a research degree (normally Ph.D.) in chemistry from a British university) IN CHEMISTRY at University College, Dar es Salaam, for research in the general field of the chemistry of the natural products—The Inter-University Council, 33 Bedford Place, London, W.C.1.

GRADUATE (with an honours degree in chemistry and zoology from a British university) to work on a 3-year programme of lipid research—The Reader in Chemical Pathology, Westminster Medical School, Research Laboratory, Udall Street, London, S.W.1.

LECTURER (well qualified in electrical engineering or physics and research experience to at least the doctorate level) in the DEPARTMENT OF ELECTRICAL ENGINEERING—Prof. J. H. Calderwood, Royal College of Advanced Technology, Salford, Lancs.

PHYSICAL CHEMIST (preferably Ph.D. and experience in the fields of spectroscopy, photochemistry or polymer characterization) for basic research—The Director, Arthur D. Little Research Institute, Inveresk, Musselburgh, Midlothian.

PRINCIPAL LECTURER in SOCIOLOGY—The Registrar (RS), Portsmouth College of Technology, Hampshire Terrace, Portsmouth, Hampshire.

PROFESSOR OF MICROBIOLOGY—The Registrar, The University, Reading.

SENIOR LECTURER or LECTURER in BIOCHEMISTRY in the School of Pharmacy—The Registrar (RS), Portsmouth College of Technology, Hampshire Terrace, Portsmouth, Hampshire.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

Building Research Station Digest No. 75 (Second Series): Cracking in Buildings. Pp. 8. (London: H.M. Stationery Office, 1966.) 4d. [3110]

The Newsletter of the U.K. Panel on Gamma and Electron Irradiation, No. 1 (October, 1966). Pp. 7. (Oxford: Dr. E. J. Berry, Technical Secretary of Research Committee, U.K. Panel on Gamma and Electron Irradiation, c/o Radiobiology Laboratory, The Churchill Hospital, 1966.) [3111]

Meteorological Office. Geophysical Memoirs, No. 110 (Fifth number, Vol. 14): Secular Variations of the Atmospheric Circulation Since 1750. By H. H. Lamb and A. I. Johnson. Pp. 125. (Met. 0.711e.) (London: H.M. Stationery Office, 1966.) 27s. 6d. net. [3112]

The Real Flavour of Physics. By Prof. C. A. Taylor. (An Inaugural Lecture delivered at University College, Cardiff, 23rd March, 1966.) Pp. 24. (Cardiff: University of Wales Press, 1966.) [3113]

Productivity Bargaining. By Ken Jones and John Golding. (Fabian Research Series, No. 257). Pp. 39. (London: Fabian Society, 1966.) 4s. 6d. [3114]

General Register Office. The Registrar General's Quarterly Return for England and Wales, Quarter ended 30th June 1966, No. 470 (2nd Quarter 1966). Pp. 31. (London: H.M. Stationery Office, 1966.) 2s. 6d. net. [3115]

The Boundary Layer. By Prof. K. Stewartson. (An Inaugural Lecture delivered at University College London, 1 March 1965.) Pp. 26. (London: H. K. Lewis and Co., Ltd., 1966.) 5s. net. [3116]

Political and Economic Planning. Annual Report 1965-66. Pp. 16. Planning, Vol. 32, No. 498 (November 1966): Problems Facing the Teaching Profession. Pp. 193-236. 6s. (London: Political and Economic Planning, 1966.) [3117]

Ministry of Agriculture, Fisheries and Food. Fishery Investigations, Series II, Volume XXV, No. 3: The Fishery for Cockles (*Cardium edule* L.) in the Barry Inlet, South Wales. By D. A. Hancock and A. B. Urquhart. Pp. iv + 32 + 16 plates. (London: H.M. Stationery Office, 1966.) 20s. net. [411] Agricultural Research Council. Memoirs of the Soil Survey of Great Britain—England and Wales. The Soils of the Church Stretton District of Shropshire. By D. Mackney and C. P. Burnham. (Sheet 166.) Pp. vii + 247 + 9 plates. (Harpenden: Rothamsted Experimental Station, 1966.) 35s. net. [3118]

Report of the Commonwealth Economic Committee. Forty-First Report: Fish. Pp. xiv + 212. (London: H.M. Stationery Office, 1966. Published for The Commonwealth Economic Committee.) 17s. 6d. net. [3119]

University of Oxford. Annual Reports 1964-1965. Pp. 27. (Supplement No. 10 to the *University Gazette*, Vol. 96, August 1966.) (Oxford: The University, 1966.) 2s. 6d. [911]

British Antarctic Survey. Scientific Reports. No. 44: The Geology of the South Shetland Islands. 3: The Stratigraphy of King George Island. By Dr. C. M. Barton. Pp. 33 + 2 plates. 18s. net. No. 52: The Petrology of Stonington and Trepassey Islands, Marguerite Bay. By Dr. A. G. Fraser. Pp. 51 + 6 plates. 30s. net. (London: British Antarctic Survey, 1966.) [1011]

### Other Countries

Centro de Cooperación Científica de la Unesco para América Latina. Monografías 1: Progresos en Biología del Suelo: Actas del Primer Coloquio Latinoamericano de Biología del Suelo. (Realizado en la Universidad Nacional del Sur Bahía Blanca (Argentina), 13-17 Octubre 1965.) Pp. xvii + 715. (Montevideo, Uruguay: Unesco, Latin American Science Co-operation Office, 1966.) [111]

Forest Research Institute, Dehra Dun. Indian Forest Leaflet No. 176 (Entomology): Termite Control Service at the Forest Research Institute and College, New Forest Estate, Dehra Dun. By P. N. Chatterjee and R. S. Thapa. Pp. 4 + 1 plate. (Delhi: Manager of Publications, 1966.) Rs. 0-80; 1s.; \$0.20. [111]

Publications de l'Université Officielle du Congo, à Lubumbashi. Vol. 13: A la Recherche de Racine Chez Marcel Proust. Albertine, Ma Soeur, de Quel Amour Blessée... Par James LeB. Boyle. Pp. 18. (Lubumbashi: Université Officielle du Congo, 1966.) [111]

American Museum Novitates. No. 2237 (December 17, 1965): Systematic Notes on the Bird Family Cracidae. No. 4: *Ortalis garrula* and *Ortalis ruficauda*. By Charles Vaurie. Pp. 16. No. 2250 (July 8, 1966): Systematic Notes on the Bird Family Cracidae. No. 5: *Penelope purpurascens*, *Penelope jacquacu*, and *Penelope obscura*. By Charles Vaurie. Pp. 23. No. 2251 (July 8, 1966): Systematic Notes on the Bird Family Cracidae. No. 6: Reviews of Nine Species of *Penelope*. By Charles Vaurie. Pp. 30. (New York, N.Y.: The American Museum of Natural History, 1965, and 1966.) [111]

Food and Agriculture Organization of the United Nations. Report of the Joint FAO/WHO Technical Meeting on Methods of Planning and Evaluation in Applied Nutrition Programs, Rome, Italy, 11-16 January 1965. Pp. vi + 77. (Rome: Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1966.) 4s.; \$0-80. [111]

South Australia. 27th Annual Report of the Council of the Institute of Medical and Veterinary Science, July 1964-June 1965. Pp. 76. (Adelaide: Institute of Medical and Veterinary Science, 1966.) [111]

Svenska Linné-Sällskapet's Arsskrift, Årg. XLVIII, 1965. Pp. 89. (Uppsala: Svenska Linné-Sällskapet, 1966.) [111]

Australia: Commonwealth Scientific and Industrial Research Organization. Bulletin No. 285: Scientific and Common Names of Insects and Allied Forms Occurring in Australia. Edited by F. J. Gay. Pp. 52. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1966.) [311]

United States Department of Commerce: National Bureau of Standards. Technical Note 403: Microchemical Analysis Section—Summary of Activities July 1965 to June 1966. Edited by John K. Taylor. Pp. x + 77. (Washington, D.C.: Government Printing Office, 1966.) \$0-50. [311]

Pan American Health Organization. Pan American Sanitary Bureau, Regional Office of the World Health Organization. Scientific Publication No. 142: Migration of Health Personnel, Scientists, and Engineers from Latin America. (Report prepared by the PAHO Subcommittee on Migration for the PAHO Advisory Committee on Medical Research.) Pp. ix + 118. (Washington, D.C.: Pan American Health Organization, 1966.) [411]

Annals of the New York Academy of Sciences. Vol. 115, Article 3: Alcohol and Food in Health and Disease. By Giorgio Lolli and 14 other authors. Pp. 787-882. (New York: New York Academy of Sciences, 1966.) \$4. [411]

United States Department of the Interior. Fish and Wildlife Service: Bureau of Commercial Fisheries. Statistical Digest No. 58: Fishery Statistics of the United States 1964. By Charles H. Lyles. Pp. ii + 541. (Washington, D.C.: Bureau of Commercial Fisheries, 1966. Available from U.S. Government Printing Office.) \$2.50. [411]

National Science Foundation. NSF 66-21: Current Projects on Economic and Social Implications of Science and Technology, 1965. Pp. v + 187. (Washington, D.C.: National Science Foundation, 1966. Available from U.S. Government Printing Office.) \$0-65. [411]

New Zealand Meteorological Service, Department of Civil Aviation. Misc. Pub. 109: Meteorological Observations for 1963—Stations in New Zealand and Outlying Islands, including the Cook Group. Pp. 100. (Wellington, New Zealand: Government Printer, 1966.) [411]

United States Department of the Interior: Geological Survey. Bulletin 1198-F: Phytocology of a Greenstone Habitat at Eagle, Alaska. By Hansford T. Shacklette. Pp. iii + 36. Water-Supply Paper 1535-K: Chemical Composition of Rainfall, Eastern North Carolina and Southeastern Virginia. By Arlo W. Gambell and Donald W. Fisher. Pp. v + 41 + plate 1. \$0.65. Water-Supply Paper 1949: Quality of Surface Waters of the United States 1963. Parts 5 and 6: Hudson Bay and Upper Mississippi River Basins, and Missouri River Basin. Prepared under the direction of S. K. Love. Pp. x + 411. \$1.50. Professional Paper 422-I: An Approach to the Sediment Transport Problem from General Physics. By R. A. Bagnold. Pp. v + 37. \$0.85. (Washington, D.C.: Government Printing Office, 1966.) [411]

National Science Foundation. NSF 66-15: Basic Research, Applied Research, and Development in Industry, 1963. (A Final Report on a Survey of R and D Funds, 1963, and R and D Scientists and Engineers, Jan. 1964.) Pp. vii + 185. (Washington, D.C.: National Science Foundation, 1966. Available from U.S. Government Printing Office.) \$1. [411]

## GOVERNOR AND PRESIDENT

MR. RONALD REAGAN seems bent on validating the predictions of those among his political opponents who were saying, only a few weeks ago, that he could not fail to be a bad governor of California. In retrospect, possibly when it comes time to stand again for election in 1970, he may reflect that it was foolish to have brought the differences between himself and others on the administration of the University of California so crudely to a head. It may now seem smart to have organized the dismissal of the president of the state university within three weeks of taking office, but a few years from now, when the governor will be a little more used to the exhilaration of power, it will not seem particularly remarkable to him that a man with the right to appoint to the Board of Regents should also have power over those the regents appoint. With luck, he may by then appreciate that it is a good deal easier to do serious damage to intellectual institutions such as universities than to work improvements on them. But Mr. Reagan has not lacked good advice, only the sense to listen to it.

It is, of course, too soon to know what will be the effects of Mr. Reagan's brashness on the welfare of the great university over which political chance has given him authority, but it is important to be clear why his doings in the past few days are reprehensible. The dispute about tuition fees at the University of California, important though it may be, is not the central issue. Whether the time has come in California for the state university to follow the precedent of most others in the United States (*Nature*, 213, 222; 1967) and to ask its students to pay tuition fees is necessarily a difficult question, with a case to be made on each side. The hard core of Mr. Reagan's offence is that he has forced his own view on the University of California in such a way as to make it plain that he is insensitive to the need that universities—wherever they are—should enjoy a real measure of independence in the running of their affairs. To scorn this principle is an assault on civil liberty as real as to suppose that newspapers can be censored with impunity, or judges bribed. And if Dr. Kerr has been sacked because he was stubborn about tuition fees, who can be sure that his successor will not be sent packing on some issue bearing even more directly on the right of the university to determine what to teach, and how.

The next few weeks will be important. The first rumblings from the campus at Berkeley suggest that the sacking of Dr. Kerr may canalize the formidable energies of the student body there away from the exotic causes which have in the past caused the new governor such pain into a protest against this affront to the independence of the university. Rough justice, some will say. But in the long-term interests of the

university, an early return to near normality would be best. The governor himself could do a lot to help, chiefly by providing some tangible assurance that the sacking of Dr. Kerr is not—as some speeches during his election would suggest—the first move in a serious assault on the university. Much, of course, will depend on the new president, whoever he will be. If Mr. Reagan has learned anything from his first blunder, it should be that the new man should be known to be at least as staunch a defender of academic freedom as Dr. Kerr. To appoint a yesman may seem politically expedient, but it would be disastrous for the university. Before the staff and students go cheerfully back to work, they have every reason to ask for assurance on this point. It would also be reasonable to ask for a clearer definition of the way in which the Board of Regents is empowered to act. If, as it should, the board can hire and fire the president of the university, it cannot also be empowered to initiate and to implement new policies without making each difference of opinion with the president, however legitimate, seem an occasion for dismissal. The ideal would be some real separation between the academic administration of the university and the making of political decisions about the scale on which it should be supported from public funds. Unfortunately, to judge from what Mr. Reagan has been saying, there is a danger that the politicians will seek an even firmer grip on what happens at the university.

And what is at stake? Mr. Reagan's previous career as a film star may not have equipped him to appreciate how critically the intellectual well-being of a university depends on the sense of freedom which people—students as well as staff—enjoy. Certainly he cannot have realized that the capacity of his university to attract talented recruits from all over the world—not just the United States—is a simple proof of the esteem in which the university is held. His first duty is naturally to the taxpayers of California, but it is unthinkable that they would wish him to cause irreparable damage to an institution which is even more widely admired than their climate. And it is also, of course, unthinkable that all of them can be as indifferent as Mr. Reagan seems to be to the benefits which society derives from independent universities.

## ALSO IN BRITAIN

THERE is an ironic echo of what has been happening in California in the special report on *Parliament and Control of University Expenditure* by the Public Accounts Committee of the House of Commons

(H.M.S.O., £1 10s.). Not for the first time, but with more persistence than is their custom, members of Parliament are seeking closer control of the details of university administration in Britain. Their present interest, the nub of the new report, is that the Comptroller and Auditor-General should be given regular access to the books of British universities. The committee insists that it is concerned only with seeing that public money is spent without impropriety, and it is understandable that anxiety on this score should have grown in the past two decades, during which the scale of public support for universities has multiplied fifty-fold to £211 million in the present academic year. But the fallacy is that even the candle-counting operation which the parliamentarians hanker for is inseparable from unwarrantable and necessarily ill-informed interference with academic matters.

The difficulty of separating accountability for detailed expenditure from policy issues should by now be thoroughly familiar. Under the British system, accountability to Parliament is the responsibility of the Permanent Secretary of the department to which money is voted. But no Permanent Secretary worth his salt would shoulder the task of asking universities how they spend their money without asking at the same time for their reasons. To attempt to behave differently would be at once futile and an assault on the view that, in the control of public expenditure, old-fashioned book-keeping should be replaced by more modern techniques of management. In the process, the Department of Education and Science would be caught up in enquiries into the uses made of particular equipments and buildings, and a great deal of detailed policy would have to be decided in Curzon Street, not in the universities. But this is not what Parliament wants. The public interest requires a continuing assurance that public money is well spent, but the University Grants Committee exists to provide just that. Parliament and the Department of Education and Science have a right to press for closer and more professional study of the ways in which universities make policy decisions and use the facilities with which they are equipped. They should also be encouraged by progress in the past eighteen months. But there is no case for more direct control of university administration. The example of the University of California should be a salutary example of the trouble that can bring.

## READY TO GO

THE Zuckerman committee (see page 325) has emerged a more healthy looking creature than seemed likely and even possible only a few weeks ago. By most tests, it is a strong committee. Its members are able, experienced and influential. It is particularly pleasing that the committee now formed includes several members of the Council for Scientific Policy, for that is at once an assurance that the expertise which Sir

Harrie Massey's committee has built up in the past two years will not be overlooked, and at the same time an assurance that the new committee will not be tempted to spend its time ferreting out generalizations about the research councils and the administration of civil science as a whole, for this is the part of the spectrum in which there is least to be unhappy about. Whether, in the long run, the advisory council will be able to become the particular kind of representative body which the Prime Minister seemed to have in mind right at the beginning is another matter. Because it is a Cabinet committee, its members must be appointed and not elected by the societies which they might be held to represent. It follows, of course, that the Zuckerman committee can claim to represent the scientific community as a whole only to the extent that its members command respect—which they do. This is, of course, the best arrangement, because both the committee-men and the learned societies are then free to say what they think. Since it is by no means beyond the bounds of possibility that the advisory council and the learned societies may one day find themselves at odds, this is a point well worth remembering.

But what will the advisory council advise on? And what kind of advice will it be tempted to give? As yet there are only the most fleeting hints of what may turn out to be possible. Much will depend on how quickly the committee can win for itself, within the government machine, the right to have a say about the important decisions which are being made by the Ministries of Defence and Technology. As luck will have it, the past week or so has provided several examples of matters which affect the pattern of scientific effort in the United Kingdom, and which seem to have been determined—not necessarily wrongly—without a detailed appreciation of all the consequences. The Anglo-French project for building a variable geometry military aircraft for the mid-seventies is a case in point. Mr. Denis Healey, the Minister of Defence, arrived in London from Paris with the assertion that the decision to commit £250 million to this project "will be a tonic to the aircraft industry", and so it seemed. But is it really wise to spend this sum of money, and a similar amount in France, on an option to keep in being aircraft manufacturing capacity which may never be profitable? If there is a case for thinking that Britain, or Europe, may one day make money by selling aircraft, might it not have been better to build something even more advanced than a Mach 3 aircraft? Or would it be better to invest in computers or hovercraft instead? Perhaps the most important need is to inform decisions about technical matters by government departments with an appreciation of the economics of innovation. There is also valuable work to be done in redeploying the skilled manpower now employed and often under-employed in government establishments. By chance, the advisory council may be helped in its work by the refreshing realism which the Ministry of Technology seems to have brought to technical decision making in the past few weeks.

## NEWS AND VIEWS

### Ructions in California

DR. CLARK KERR, the President of the University of California dismissed by the Board of Regents on January 19, has been associated with the university for 22 years and president since 1958. His dismissal by a majority of 14 to 8 came at the end of a week of discussions within the Board of Regents of the proposals put forward by the new Governor, Mr. Ronald Reagan, for a contribution by students to tuition fees at the nine campuses of the university. The dismissal seems to have been something of a surprise, for there had earlier been rumours that a compromise would be reached between those in favour of a tuition levy and those resisting the proposal at least for the academic year beginning in 1967.

The crisis at the university has come at the end of a decade in which the university has multiplied its size by a factor of nearly four. In the current year, the running cost of its operation will be \$730 million, while new plant and equipment will cost \$145 million. (In strictly financial terms, therefore, the University of California is bigger than all the universities of the United Kingdom put together.) In practice, the State of California contributes just under a half of the cost of keeping the university going. The federal government is almost equally important as a source of funds, largely through research contracts with university departments. Altogether the university has 87,000 students, with nearly 30,000 of them on the campus at Berkeley which has been the recipient of a great deal of Mr. Reagan's vituperation against the university both in the month before his election in November last year and in the weeks since his coming to office at the beginning of January this year. Mr. Reagan has frequently referred to the events in 1964 when students complained against the university administration of lack of freedom and when outside critics of the university complained that students were given too much licence. The present dispute has come to a head, however, because of Mr. Reagan's determination to reduce the contribution of the State of California to the running of the university by an amount reported to be equivalent to ten per cent.

The immediate reaction at the university has been to suggest to some heads of departments that uncertainty about the future of the university may make it easier for other universities to tempt away members of the faculties of the nine campuses at California. As yet there is no news of a successor to Dr. Kerr, and at this stage no assurance that this appointment will be made from among the nine chancellors who serve as heads of the individual campuses of the university.

### Committee at Last

NEARLY three months after his first announcement on October 25, the Prime Minister was able to tell the

House of Commons on January 17 of the composition of the Central Advisory Council for Science and Technology under Sir Solly Zuckerman. The Prime Minister said that the members would be: Sir Eric Ashby, Master of Clare College, Cambridge; Sir Harrie Massey, Professor of Physics at University College London and Chairman of the Council for Scientific Policy; Sir Hugh Tait, managing director of Esso Petroleum Co. Ltd.; Professor P. M. S. Blackett, Deputy Chairman of the Advisory Council on Technology and Chief Scientific Adviser to the Ministry of Technology; Professor A. B. Pippard, Cavendish Laboratory, Cambridge; Professor B. R. Williams, Professor of Economics at the University of Lancaster and an adviser to the Ministry of Technology; Dr. A. H. Cottrell, Chief Scientific Adviser (Studies) to the Ministry of Technology; Dr. F. S. Dainton, Vice-Chancellor of the University of Nottingham; Dr. F. E. Jones, managing director of Mullard Limited; Mr. F. Cousins, General Secretary, Transport and General Workers Union and Minister of Technology 1964-66; and Mr. R. D. Young, Alfred Herbert Limited. The Prime Minister said that the terms of reference of the council are to advise the government "on the most effective national strategy for the use and development of our scientific and technological resources."

The strength of the new committee is widely acknowledged and held to be an assurance that it will be on the side of the angels. The Council for Scientific Policy, which at one point seemed to be in danger of being overshadowed by the new council, is strongly represented, principally through Sir Harrie Massey. However, Dr. Dainton, Dr. F. E. Jones and Professor Blackett are all members of the Council for Scientific Policy. The presence of Mr. Frank Cousins on the committee is at first sight a surprise, although Mr. Cousins was a member of the council of the Department of Scientific and Industrial Research between 1962 and 1964. The interests of the Ministry of Defence are represented by Dr. Cottrell. In the formal announcement of the committee, no reference is made to the way in which the Royal Society was originally asked to appoint a representative although, of course, Professor Blackett is also President of the Royal Society. Apparently the original intention that the council should function on a confidential basis has not been changed, although it is considered that the council will be accessible to the Select Committee on Science and Technology being formed in the House of Commons. It is considered that the new committee will begin work on attempts to secure a more effective distribution of skilled manpower within government and other public laboratories. Its hardest task is bound to be the better articulation of civil and defence research.

### Reservoirs in the Sea

THE United Kingdom is likely to be short of water within one or two decades. One possible solution to the problem is to build barrages across estuaries and bays, turning them into reservoirs. The Ministry of Housing and Local Government appointed consultants to investigate the feasibility of two such schemes, across Morecambe Bay and Solway, and the consultants' reports have now been published (H.M.S.O., *Morecambe Bay*, £1 2s. 6d.; *Solway*, 16s.; *Report*, 10s. 6d.).

So far the studies have been desk bound, and have not involved detailed engineering or geological work. Moreover, the consultants were asked to consider only the problems of water and not those of communications, power generation and amenity. Their conclusions are therefore tentative, but they suggest that both schemes are feasible. Certainly some action will have to be taken, for the river authorities foresee a shortage of about 425 m.g.d. (million gallons per day) by 1981, and 1,200 m.g.d. by 2001.

The Morecambe Bay barrage should have priority, the report concludes, because the need for water is greatest in the North West, and because the barrage would free the Lake District water for use in other areas. The storage capacity of Morecambe Bay would be 55,000 m.g., and if the barrage were built it could be supplying 500 m.g.d. by 1977-79. Inland schemes will therefore have to meet the demand until the late seventies, but a decision on barrages must be made in the early seventies if not before. The total cost of the Morecambe Bay scheme would be between £54 and £69 m, including a dual two-way highway across the barrage and full treatment works, and it is estimated that the cost of fully treated water would be between 6.7 and 8.4 pence per 1,000 g.

The water initially enclosed would of course be saline, but the consultants believe that this could be removed by filling and emptying the reservoir while the road was being built. The draining and re-filling cycle, repeated four times, would reduce the chloride content to about 100 p.p.m., and ordinary filtration equipment could be used for final purification.

## European Exchanges

THE most tangible result so far of the expressions of interest by the Royal Society in European collaboration is the announcement of a new programme of grants for financing visits by working scientists between European institutions. In a statement published a week ago, the Royal Society said that it has received "substantial financial support for the programme from several donors", and that the intention is "not only to benefit science but also to strengthen the European community as a whole". Although it is expected that a "large fraction of the funds" will be used to help British workers to travel abroad, it is also intended that they shall be used to enable scientists from the mainland of Europe to visit Britain.

The funds so far available will be spent in three distinct ways. First, there will be postgraduate fellowships, ideally for people wishing to stay a year or more at a laboratory in some other country, and with a financial basis sufficiently generous to enable recipients to live without discomfort in the places at which they settle, and even to buy modest amounts of equipment if their host laboratories cannot provide them. The Royal Society says that it has funds to enable seven or eight British scientists to go abroad under this part of the scheme, and for roughly a third as many people to stay in Britain. The programme also includes provision for what are called study visits, on which junior and senior people will spend between a week and six months at laboratories abroad, and it is thought likely that there will be money enough for 50 British scientists and 20 from abroad. In addition, there is a plan to sponsor between six and ten research confer-

ences a year, with between 25 and 100 participants and with some provision for inviting a small number of participants from outside Western Europe.

## Chrysler in Britain

THE Ministry of Technology announced on January 17 its approval of an agreement by which the Chrysler Corporation gain control of Rootes, the British motor manufacturer. In a Europe increasingly sensitive to charges of technological domination by the United States, the British Government seemed surprisingly cheerful about the takeover. There are two reasons for this; first, the Government has probably decided that only those industries using the newest technologies are worth protecting, and second, there was nobody else who would touch Rootes with a barge-pole. Chrysler was committed to Rootes by its partial takeover in 1964; at present it owns 45 per cent of the ordinary voting shares, and 66 per cent of the non-voting "A" shares. A rights issue, underwritten by Chrysler, will now be made, giving shareholders the opportunity of obtaining five shares for each four held at present. This will raise £10 m, and an additional £10 m will be raised by a 15 year loan from Chrysler.

The agreement is hedged around with some splendid sounding but somewhat symbolic safeguards. The most significant is probably the involvement of the new Industrial Reorganization Corporation, which will purchase a seat on the Board by investing £3 m. Since the I.R.C. is also arranging an export consortium arrangement for the whole of the British motor industry, it will have to be very careful to ensure that participation in Rootes does not interfere with industrial security. The other safeguards agreed to by Chrysler are that the corporation will maintain a majority of British directors on the board, continue expansion at Linwood in Scotland, put no obstruction in the way of the export of Rootes products to all "practicable" markets, and exchange directors between Chrysler International, Simca and Rootes. These safeguards are unlikely to interfere with the way Chrysler runs Rootes. Markets already controlled by Chrysler or Simca may well be considered "impracticable", but similar limitations do not seem to have affected Ford, one of Britain's best exporters, while Simca is the leading French motor exporter.

Alternative solutions, in any case, were singularly unappealing. Outright takeover by the British Government was one possibility, but Rootes has been losing money for some time—£3 m before tax in the year to last July, and nearly £5 m since then. Inevitably Chrysler had to step in to protect its earlier investment; any attempt to stop it would have been futile—and costly as well.

The British market is now divided almost equally between companies under British and American control. The British Motor Corporation and Standard Triumph Leyland make up about 48 per cent of the market, and Vauxhall, Rootes and Ford split between them an almost exactly equal share. The remainder is made up of imported vehicles, largely from Europe.

## Survey for History

THE Indian Census of 1961 included a special count of scientific manpower which has recently been published

as a monograph by K. Ray of the Council of Scientific and Industrial Research at New Delhi. While it is certainly difficult to publish census details quickly, there is a strong case for rapid publication of specific surveys such as this, which are important for planning. By now the survey is interesting only as history. In 1961 the survey showed that there were 250,000 qualified graduates in science, technology and medicine in India, of whom 6.5 per cent were women. For every 100 scientists there were 75 engineers (the United Kingdom has 130 engineers for every 100 scientists, and the United States has 250). The deployment of these graduates comes as something of a surprise; 18.6 per cent had found non-technical work, and more than 10 per cent were unemployed, although the census was carried out at the time of year when graduate unemployment in India is at a minimum. Of those who said how long they had been unemployed, more than one half had been out of work for more than a year. As the census points out, it is difficult to reconcile the high rate of unemployment among doctors (7.3 per cent) with the fact that in India there are 6,000 people for each doctor. The unemployed could best be offered the opportunity of becoming teachers, of which India has a particular need; but perhaps by now they have all found jobs.

## Doubt and Mistrust

STIRRINGS of discontent within the National Trust have come to a head with the dismissal of Commander Conrad Rawnsley from his post as Appeals Director and Director of Enterprise Neptune. Enterprise Neptune was conceived as a means of saving Britain's coastline from indiscriminate development, and has raised a large sum of money for this purpose—£900,000 by the trust's reckoning, and more by Commander Rawnsley's. In recent months, costs of the appeal have amounted to 20 per cent of receipts, which the trust considers to be too high a price to pay, and which is why the trust decided to absorb the appeal into its general administration. Commander Rawnsley disagrees: "It could have gone on to raise by the end of May 1968 £3 m at an overall cost of 7 per cent—an all time record low for an appeal of such a nature".

Certainly the trust is ill-equipped to cast itself in the role of a pauper. Since its foundation in 1907 as a means of preserving places of historic interest or natural beauty, it has grown into the third largest landowner in Britain, possessing 350,000 acres of land, investments worth £7 m and 200 historic houses. On the face of it, this looks like good management, but the Reform Movement headed by Commander Rawnsley disagrees. Under the banner of Enterprise Neptune they have mobilized a small army of supporters. Nobody quite knows how many.

On the one hand, the objectors say that the trust is undemocratic, and that its committees are self-perpetuating cliques appointed by head office. Even the local committees, they say, are unrepresentative, and there is no devolution of power. The trust already concedes that "an increasing decentralization is called for". On the other hand, the objectors claim that the trust is an inefficient manager, landowner and employer, and that the annual accounts are deliberately obscure. Only where the great houses are concerned do the

reformers feel that the trust has done a good job; they feel, however, that preservation as in *aspic* may be appropriate to great houses, but is quite inappropriate to areas of land. They want to see more development of the land, with freer access for the public, and the creation of proper camping sites.

These objections go far beyond the pique of a dismissed employee, and in fact reflect a difference of attitude as to how the trust should be run. They will be put in the form of motions to the extraordinary general meeting which the reform movement has called on February 11. Whatever the result, the controversy will do the trust no harm, and may lead to a situation in which ordinary members feel more involved in its work. In any case, the fuss is likely to have a healthy effect on recruitment.

## Mathematics and the Mantle

SPHERICAL harmonic analysis has been used in the past by the proponents of continental drift to try to demonstrate that the figure of the Earth is related to convection cells in the mantle. This approach—which considers the Earth's topography as a whole—has not been entirely satisfactory so far, because the contribution of the principal tectonic features to the analysis is obscured by the steep slopes of the continental margins. In an attempt to overcome this difficulty A. M. Coode (*Geophys. J. Roy. Astro. Soc.*, **12**, 55; 1966) has ignored the continental features and has analysed only recent tectonic features—oceanic ridges and mountain-trench systems. Because the features chosen for analysis are roughly of the same age, any confusion which arises from a temporal change in the mechanism which generates these features, and therefore a change in the features themselves, is avoided. Assuming that the ridges are tensional and that the mountain trench systems are compressional features, Coode demonstrates that the principal tectonic features of the Earth are related to a global generating mechanism of the fifth degree. Following Runcorn, he interprets the mechanism as one of a convecting mantle and also supports the hypothesis that the pattern of convection has recently changed from a dominantly four-cell to a five-cell pattern.

## Mind and Gene

SOME of the problems of the links between psychiatry and genetics are discussed in *Research on Genetics in Psychiatry*, the report of a scientific group of WHO. There is clear evidence that genetic factors are involved in the aetiology of a number of mental diseases, although the genetic factors are more obvious in some than in others. Huntington's chorea is the best example of a hereditary mental disease—family trees showing very clearly the inheritance of a single dominant gene have been compiled for a number of families in which the disease is current. In most of the more common mental diseases, schizophrenia, epilepsy and manic-depression, for example, the genetic component is far less clear cut, although it probably plays a considerable part in most of these states. The lack of a standard international nomenclature only adds to the intrinsic difficulties of these studies.

Understanding of the two general categories of mental disease is at very different levels. Mental

defect has been studied by a number of fruitful techniques and its genetic aspect is much better understood than that of mental disorder. A number of syndromes arising from chromosome defects, such as Klinefelter's syndrome (the presence of an excess sex chromosome) and Down's disease (21-trisomy), are well characterized. Not surprisingly, what the report calls "mental retardation of unknown aetiology" is poorly understood, although here the statistical methods of population genetics can be of great value. These methods have made it possible to divide the cases of retardation into two main groups—one in which it seems that there is a strong genetic involvement and one with a low risk. Genetic factors are responsible for many cases in the group at high risk. These include at least one chromosome abnormality and a number of single recessive genes with high penetrance.

The WHO group puts forward a number of proposals for topics on which work should be concentrated. It calls for research into the frequency of chromosome abnormalities and the relationship of these abnormalities with mental disorder, particularly from the biochemical point of view. It would like to see more work on twins, preferably on an international scale, including studies of twins separated in early life, and on adopted children and their families. It also thinks workers should hurry to examine inbred populations before they are submerged by admixture and the spread of urbanization.

## New Ghost Town

THE new town promised by the Minister of Housing and Local Government in North Buckinghamshire will not only be the largest in the United Kingdom but probably the most diffuse as well. By the end of the century it will hold 250,000 people from London at an overall density of about 11 to the acre. Most of the new town, to be called Milton Keynes, will be between the trunk roads M1 and A5, and it will absorb the existing towns of Bletchley, Wolverton, and Stony Stratford. The original plans specified an area of 25,200 acres, but the report of the public inquiry conducted by Mr. G. C. Godber, an independent inspector appointed by the ministry, has persuaded Mr. Greenwood to reduce this by 3,300 acres. Observing that the site is roughly as large as Bristol (population 434,000) and substantially larger than Coventry (327,000), the inspector reported that "The objectors were not convinced and I am certainly not convinced that it can be right to take so low a density as a target . . . One thing is certain—the plan will fill whatever land is designated, and it is not right to sacrifice good farms and good farmers needlessly to make a planners picture."

Not all the planners are cock-a-hoop at the opportunity offered by the minister, however. There are two schools of thought—at least—on town density. One, in which architects are conspicuous, holds that high densities are necessary both as a discipline and to create what is known as urbanism (or occasionally urbanity, although that is usually taken to mean something quite different). This point of view is coloured by sociological studies such as that of Michael Young and Peter Wilmott—*Family and Kinship in East London*—who showed that when people are moved from a close-knit community (Bethnal Green) to a

suburban housing estate (Woodford), their strong sense of community is left behind. Among the greater population densities used, with the support of many local authorities and the Ministry of Housing, is that at Cumbernauld new town in Scotland, where 85 people are housed on each acre.

The other point of view is probably put most forcefully, and certainly most often, by the Town and Country Planning Association, whose attack is directed chiefly at flats, which are said to be unpopular with tenants, and more expensive to build and maintain than houses. Certainly the association is convinced that only about 5 per cent of British people want flats, and that even this minority taste is probably declining. Bungalows, semi-detached and detached houses vie for popularity. To those for whom this presents a doleful vision of mile upon mile of suburban houses and bungalows, combining the worst features of American urban sprawl and British design, the association says that urban sprawl is not necessarily the result of low density housing but simply of bad design.

The aesthetic and sociological argument is a fascinating one, but may become an irrelevance, if it has not already done so. The South-East Study (H.M.S.O., 15s., 1964) estimates that the population increase of South-East England is likely to be 3.5 million by 1981. Housing this increase in towns as thinly spread as Milton Keynes would need an area of about 310,000 acres—greater than that of Bedfordshire. Nobody dares to think about A.D. 2000, when the new town will have reached its leisurely target.

## Cinnabar with Everything

THE production of gold from base metals has long been known as the ambition of the alchemists, but they had another preoccupation—the lengthening of life. Chinese alchemy in particular was almost totally dedicated to this end, as can be told from *A History of Ideas about the Prolongation of Life* (Trans. Amer. Phil. Soc., N.S., 56, part 9; 1966).

One of the principles of the Chinese alchemists was a kind of vitalism, which implied that certain substances contain the essence of life and can be used to produce medicines which help to prolong it. Certain characteristics were considered necessary for a substance to be a vitalizer; these included being shining, fluid, strong to the taste and blood red in colour. The alchemists had a list of materials which possessed the vitalizing property, and there was a hierarchy with minerals at the top and herbs at the bottom. Drugs of vegetable origin were inefficient vitalizers; they can only decompose and decay, but the minerals had many of the necessary characteristics. The most valuable were the rare minerals. Silver, gold and cinnabar were at the top of the list; mercuric sulphide occupied a supreme position in Chinese alchemy, although it was only of minor importance in other cultures. Cinnabar had the blood-red colouring which bestowed life giving qualities, which were already recognized, for neolithic people in China had deposited vermilion pigment with their dead. The change of cinnabar, on heating, to mercury, and the conversion of this to mercuric oxide which sublimes back to mercury, showed the alchemists a seemingly endless cycle involving "living" red cinnabar and "living" fluid mercury. This represented longevity, which

man could increase by taking medicines prepared from cinnabar.

## Isolation of a Repressor Molecule

from a Correspondent in Biochemical Genetics

In 1961 Jacob and Monod proposed a scheme to explain how the activity of genes might be controlled. Their theory was constructed from observations on the lactose operon of *E. coli*, a cluster of three genes which code for three enzymes, two of which are necessary for the utilization of the sugar lactose and other  $\beta$ -galactosides. When wild type *E. coli* is grown with glycerol as a carbon source, all three enzymes are present only in very small amounts. Addition of  $\beta$ -galactosides and, in particular, a non-utilizable  $\beta$ -thiogalactoside, induces a high rate of synthesis of these enzymes. There are at least two regions on the *E. coli* chromosome concerned with the regulation of the lactose operon—a regulator gene and an operator region. Jacob and Monod proposed that the regulator gene codes for a regulator molecule, or repressor, and that this combines with the operator region adjacent to the three structural genes so as to prevent the reading of the operon. The repressor molecules were also supposed to recognize  $\beta$ -galactosides with the result that they were removed from the operator region by the formation of a  $\beta$ -galactoside—repressor complex. This sequence of events would now allow the expression of the lactose operon, probably by permitting the synthesis of a messenger RNA.

The regulator gene has recently been shown to have properties which show that the repressor is a protein molecule. Insight into the molecular mechanism of regulation has, however, rested only on indirect experiments because it has not been possible to detect and assay repressor molecules in the test-tube. The whole status of the field has now been altered by the recent work of Professor Walter Gilbert and Dr. Benno Müller-Hill of Harvard University, who have detected the repressor molecule for the lactose operon (*Proc. U.S. Nat. Acad. Sci.*, **56**, 1891; 1966). Their assay depends on the ability of the repressor to bind an inducer  $\beta$ -galactoside. Using a radioactive inducer, they showed by equilibrium dialysis that more inducer was found inside the dialysis bag containing a cell extract than outside the bag. Control experiments on extracts from cells which contain a deletion of the regulator gene show that these do not bind radioactive inducer. They have shown that this repressor is a protein molecule with a probable molecular weight of about 150,000–200,000, and that there are about ten molecules of repressor per gene copy in *E. coli*.

This is the first and crucial step towards the biochemical study of the control of gene expression.

## Enzyme Mechanisms

from a Correspondent in Molecular Biology

THE power of relaxation methods for the measurement of fast chemical processes is nowhere more spectacularly revealed than in the temperature-jump studies of enzyme kinetics which have been emerging from a number of laboratories. This month a further study on ribonuclease throws new light on the mechanism of

the enzyme, and an important article from the laboratory of Eigen goes some way towards defining the characteristics of an allosteric system of interacting sites.

Erman and Hammes (*J. Amer. Chem. Soc.*, **88**, 5607 and 5614; 1966) have used a stopped flow temperature-jump technique to study the interaction of both cytidine 2':3'-cyclic phosphate and cytidylyl-3':5'-cytidine with ribonuclease. In this system the usual temperature-jump method fails because the equilibrium is overwhelmingly biased in favour of the product of hydrolysis—cytidine 3'-phosphate—and its complexes with the enzyme. By introduction of the stopped flow, the temperature jump can be applied 16 msec after the mixing of enzyme and substrate. The system is found to exhibit two relaxation processes, one independent of concentration at high excess of substrate, the other dependent on it. These are attributed respectively to an isomerization in the enzyme-substrate complex and to the binding of the substrate to the enzyme. Taken together with earlier work on the interaction with cytidine 3'-phosphate, a mechanism for the hydrolysis of the substrate has been evolved which appears to account for all relaxation, equilibrium and steady-state data. Moreover, the pH-dependence of the relaxation processes is interpreted as indicating the existence of five states of the enzyme-substrate complex, involving three or more ionizing groups in the enzyme, with specified  $pK$ 's. Parallel reaction paths are also inferred.

In the accompanying article, the same authors consider the ribonuclease-cytidylyl-3':5'-cytidine system, which is shown to have similar characteristics. It is recognized that there is at present no means whereby the formalism relating the states of the system can be interpreted structurally. To the extent that certain groups, among them two histidines, are believed to be present in the active centre, a number of speculations are possible, but this is another case in which the results of crystallographic analysis of the protein are eagerly awaited.

An article by Kirschner *et al.* (*Proc. U.S. Nat. Acad. Sci.*, **56**, 1661; 1966) examines the binding of NAD to glyceraldehyde-3-phosphate dehydrogenase, an enzyme known to contain four identical sub-units. The system was selected because it was believed to represent a tractable case of "homotropic" ligand binding. Three relaxation processes in substantially different time ranges were observed, so that the dependence of each step on concentration could be determined. If it is assumed that conformational transitions are slow in comparison with bimolecular binding processes, the three relaxation times can be used to derive rate constants. The kinetics can be very satisfactorily accounted for in terms of the postulates of the appropriate allosteric hypothesis—that the apoenzyme exists only in two tetrameric modifications and that the intrinsic dissociation constants of the binding sites are identical in both forms. It is also shown that there is a high degree of co-operative (all-or-none) behaviour between the sub-units. These results can evidently be most simply explained in terms of the allosteric theory, for which they may be regarded as providing support. As the authors point out, it will be of considerable interest to obtain similar information on a range of other sub-unit enzymes, and to see which generalizations appear to survive.

## Parliament in Britain

IN a written answer in the House of Commons on January 17 the Joint Parliamentary Secretary to the Ministry of Technology, Dr. J. Bray, said that the ministry was supporting the development of fluid logic devices for computer peripherals by two contracts under the Advanced Computer Techniques Project. One was with British Telecommunications Research, Ltd., and the other with International Computers and Tabulators, Ltd.; both were for 18 months and the ministry was paying half the total cost of each, £52,000 and £50,000, respectively. The aim of the contracts was the development of cheap individual fluid logic elements and of complex integrated arrays of fluid logic elements to perform particular logical functions.

IN a written answer in the House of Commons on January 19, the Secretary of State for Education and Science, Mr. A. Crosland, stated that Parliament would be asked to vote funds to meet the additional cost for all overseas students financed from British official sources (including the British Council), mostly from developing countries. A fund would also be provided to reimburse the additional £50 payable by students already embarked on courses and who were financed by the governments of developing countries. No part of the fees of overseas students was met directly by his Department, but even after the recently announced increase in fees, public funds would still be providing on average some two-thirds of the recurrent costs of overseas students at universities and colleges of further education.

REPLYING to a question in the House of Lords on January 19 regarding university fees of overseas students, the Parliamentary Under-Secretary of State for Commonwealth Affairs, Lord Beswick, said that while the Government did not lay down fees to be charged by the universities, it had decided that the next quinquennial settlement of recurrent grant to universities should assume a free income of £250 a year from overseas students starting on courses in the next academic year. To avoid hardship, the increase in the fee assumed for those who had already started on courses extending into the next academic year would be limited to £50 a year for the remainder of their present course. The decision was taken in the light of the recommendations of the Robbins Committee and the Select Committee on Estimates that the general level of fees should be increased to meet at least 20 per cent of expenditure. For most United Kingdom students the general effect would be to transfer expenditure from central to local government. The existing fee structure resulted in a concealed subsidy to overseas students at United Kingdom universities which had grown from £3-4 million in 1955-56 to about £12 million in 1965-66. Even with the increased fee, this element of subsidy would be higher than it was 5 years ago. Some 30 per cent of overseas students came from countries such as the United States, Canada and the Scandinavian countries.

MR. GORONWY ROBERTS, replying to a question on January 19, said that during 1963-64 a total of 605 graduates of United Kingdom universities emigrated to the United States—298 had first degrees and 307 higher degrees.

## University News: California Institute of Technology

THE California Institute of Technology has announced that the new Robert Andrews Millikan chair in physics will be held by Professor Murray Gell-Mann. Dr. Gell-Mann has been associated with the California Institute of Technology since 1955 and is distinguished for his contributions to the theory of fundamental particles and in particular for his introduction of the concepts of "strangeness" and the "eight-fold way", the second of which has provided a framework within which it may be possible to classify the particles. Dr. Gell-Mann also pointed to the value of "quarks" as a means of rationalizing relations between different particles.

London

DR. K. A. PORTER, reader in morbid anatomy at St. Mary's Hospital Medical School, has been appointed to the chair of pathology, tenable at that school.

Manchester

DR. T. S. L. BESWICK, at present reader in virology, has been appointed to the newly established chair of virology as from February 1. Dr. Beswick is known for his work on poliomyelitis vaccines and the experimental pathology of virus diseases.

University College of Swansea

DR. P. J. SYRETT, reader in botany in University College, London, has been appointed professor of botany in succession to Professor H. E. Street.

## Appointments

DR. R. H. SIMPSON, associate director of the United States Weather Bureau, has been appointed director of the National Hurricane Centre in Miami, in succession to Dr. G. E. Dunn. Dr. Simpson will be succeeded by K. R. Johannessen, at present director of ESSA-Weather Bureau's Eastern Region.

## Announcements

SIR ROBERT WYNNE-EDWARDS has retired as chairman of the Council of Engineering Institutions, a post which he has held since the council was established. A graduate of Christ Church, Oxford, he spent many years in Canada before returning to Britain in the 1930's, and during the Second World War he worked in the Ministry of Works. After the War he returned to private industry, and was managing director of Costain-John Brown (later Constructors John Brown Ltd.) from 1948 until 1961; he has also served as member and chairman of the Building Research Board and the Coal Research Board, and became president of the Institution of Civil Engineers in 1964. He will be succeeded as chairman of the C.E.I. by Mr. H. N. Pemberton, who has represented the Institute of Marine Engineers on the board of the C.E.I. since 1964. Mr. Pemberton has been a member of the Ministry of Power nuclear safety advisory committee and of the marine engineering and atomic energy committees of the British Ship Research Association, as well as vice-president of the Institute of Marine Engineers.

MR. H. J. BUNKER has been elected president of the Institute of Biology. Dr. T. G. Onions has been elected honorary secretary and Dr. J. A. Freeman honorary treasurer of the institute.

THE gold medals of the Royal Astronomical Society have been awarded to the following: PROFESSOR H. ALFVÉN, Royal Institute of Technology, Division of Plasma Physics, Stockholm, for his fundamental work on cosmical electrodynamics; DR. A. R. SANDAGE, Mount Wilson and Palomar Observatories, for his fundamental work on stellar evolution and the history of the galaxy, and in providing optical data basic to modern cosmology. The

Eddington medal has been awarded to PROFESSOR R. F. CHRISTY, California Institute of Technology, for his work on the non-linear theory of pulsating stars.

THE Steacie Prize for 1966, which consists of a cash award of \$1,200, has been awarded to Professor G. H. Dixon of the University of Columbia for his important work on the synthesis of insulin and on the structure of haptoglobins.

THE Royal Society of Arts has awarded the Benjamin Franklin Medal for 1967 to Dr. Detlev Wulf Bronk, president of the Rockefeller University in New York.

DR. EDWARD M. PURCELL, professor of physics at Harvard University, has been awarded the Oersted Medal by the American Association of Physics Teachers.

THE American Microchemical Society has created a fund to commemorate the work of the late Dr. A. A. Benedetti-Pichler. The award will be made to an individual who has made outstanding contributions to the practice or teaching of microtechniques. The recipient will give a lecture at a gathering of analytical chemists. Nominations must be in the hands of the committee by April 1, 1967. A letter of 300 words or fewer, giving the name and address of the nominee and citing, in general, his work, may be sent to the chairman of the 1967 Committee, Dr. Leo K. Yanowski, Department of Chemistry, Fordham University, New York, N.Y., 10458.

PROFESSOR P. M. S. BLACKETT will give the 1967 Chelsea Lecture on the subject "Continental Drift" at Chelsea College of Science and Technology on February 7. This is the first of a series of lectures established to commemorate the admission of the college as a school of the University of London.

THE fourth symposium on "African Geology" will be held in the University of Sheffield during April 19-22. Further information can be obtained from Mr. P. Wilkinson, Department of Geology, University of Sheffield, St. George's Square, Sheffield, 1.

A CONFERENCE on "Inorganic Reaction Mechanisms", sponsored by the Irish National Committee for Chemistry and Professor F. L. Scott, of University College, Cork, will be held in Kinsale, Co. Cork, during April 10-14. Further information can be obtained from Dr. N. Mulcahy, Chemistry Department, University College, Cork.

THE second United Kingdom Automation Council control convention on "Advances in Computer Control" is to be held in the University of Bristol during April 11-14. Further information can be obtained from the Convention Secretariat, The Institution of Electrical Engineers, Savoy Place, London, W.C.2.

A SYMPOSIUM on "Liquid-Liquid Extraction", organized by the Northern Branch of the Institution of Chemical Engineers, will be held at the University of Newcastle upon Tyne during April 20-21. Further information can be obtained from the Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

A CONFERENCE on "New Developments in Optics and their Applications in Industry", organized by the British Scientific Instrument Research Association, will be held in Eastbourne during April 11-12. Further information can be obtained from Mr. P. J. Geary, Publicity and Literature Services Department, SIRA, South Hill, Chislehurst, Kent.

A SYMPOSIUM on "Mean Sea Level", organized by the International Association of Physical Oceanography with the support of the United Nations Educational, Scientific and Cultural Organization, will be held in Washington during April 13-15. Further information can be obtained from Mr. S. D. Hicks, Coast and Geodetic Survey, U.S. ESSA, Washington Science Center, Rockville, Maryland.

A CONFERENCE on "Image Detection and Processing", organized by the Optical Group of the Institute of Physics

and the Physical Society, will be held at the Royal Radar Establishment, Great Malvern, during April 24-26. Further information can be obtained from the Meetings Officer, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A CONFERENCE on "The Teaching of Mathematics to Physicists", arranged by the Education Group of the Institute of Physics and the Physical Society in collaboration with the Institute of Mathematics and its Applications, will be held in the University of Exeter during April 12-14. Further information can be obtained from the Meetings Officer, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A SYMPOSIUM on "The Use of Isotopes and Radiation in Plant Pathology Studies", organized by the Food and Agriculture Organization of the United Nations and the International Atomic Energy Agency, is to be held in Vienna during April 17-21. Further information can be obtained from Mr. Nils Lund, Division of Public Information, International Atomic Energy Agency, Karntner Ring 11, A-1010 Vienna.

## CORRESPONDENCE

### Doomsday 1967

SIR,—As one of the participants in the BBC programme "Challenge" broadcast on January 5, I would like to express agreement with all of the comments in your leading article of January 14. My own contribution, as recorded, consisted of three parts. The first showed what might be unpleasant effects of our elimination of all previously effective limits on world population if we fail to develop new ones. The second started with the comment that naturally I do not believe for a moment that any such catastrophe will be allowed to occur and went on to point out that there have already been developed new methods, the most important being practical means of birth control. The Japanese have already demonstrated the effectiveness of these by cutting their net reproduction rate from 2 to 1 in less than 20 years. The third part pointed out that we have now for the first time a choice as to whether we limit the population, and if we do, a wide range of choices of how to do it. The whole was consistent with my belief that the fundamental value to the world of science and technology is that it gives us greater freedom of choice both of action and in thought.

The first alone of these three parts was broadcast.

I consider it perfectly fair for the BBC to stress the disadvantages of wrong choices, and hence the danger of carelessness in making them. But to omit altogether the advantages of the choices which have been made and the huge range of alternatives which we could make seems to me, as to you, a serious distortion. I am not complaining that the producer of the programme deceived me in any way; rather my lack of experience may have misled him. I had not seen any of the other contributions when I made my recording and it did not occur to me to ask that, if reduction of my allotted time were necessary, my share should be cut down in a balanced way.

Nevertheless, if I had known that there would be time for the first aspect only of my contribution, I would have preferred not to take part at all.

Yours faithfully,

J. H. FREMLIN

Department of Physics,  
University of Birmingham.

# Organization for Science

by our Special Correspondent

Mr. Anthony Crosland, Secretary of State for Education and Science, is responsible for the administration in Britain of public support for scientific research and for the universities. The following is the outcome of an interview on January 18—the day after the membership of the Zuckerman committee was announced in the House of Commons.

THE Zuckerman committee will be able to do a useful job without disturbing the existing machinery for the administration of civil science in Britain. This is the view of Mr. Anthony Crosland, Secretary of State for Education and Science. He said that there was a "case for a committee looking at the whole field" of civil science, technology and defence.

In Mr. Crosland's view, it is probable that the committee will not wish to concern itself directly with the administration of the research councils—the field in which the Council for Scientific Policy under Sir Harrie Massey operates. The Minister seems to be happy with the way in which his own parish is being regulated, and clearly does not consider that there is much that outsiders would find to criticize in his own machinery for dealing with the research councils. That said, however, he is as ready as anybody to confess that it would be a great help if somebody could design rules to indicate the optimum level of spending on science and technology, as a whole and as separate parts.

Mr. Crosland considers that the membership of the Zuckerman committee is an assurance that some hypothetical dangers will not materialize. In particular, he does not consider that the existence of a strong central committee will give the Government too much control. The "guarantees against that danger" are the men who belong to the committee, many of whom have had several years of experience as independent advisers to the Government.

The new committee, being a Cabinet committee, will function in private, and Mr. Crosland does not consider that it will be much scrutinized by the Select Committee on Science and Technology which is to be set up in the House of Commons in the months ahead. He considers that the parliamentary committee will be valuable because its field is one of "those grey areas in which you never get parliamentary debates" which provide opportunities for Members of Parliament fully to satisfy their curiosity. Mr. Crosland emphasized the educational role of the committee, especially to begin with. It "won't start off with the research councils" and, while recognizing that it might be unfortunate if the parliamentary committee were used as a platform for sensation, he hoped that it would exercise its prerogative to open its meetings to the public.

Given the rumours—or the hopes—there have recently been of massive public support for some schemes for European collaboration in academic science, Mr. Crosland had a moderately optimistic tale to tell. In the field of fundamental research the Government—prompted by the Council for Scientific Policy and supported by the Royal Society—has taken an initiative in O.E.C.D. to work out a system of international fellowships. The creation of what the Prime Minister has called a European technological community is, of course, the responsibility of the Ministry of Technology and not of the Department of Education and Science.

On the administration of the universities, Mr. Crosland is anxious to make it clear that the universities have in the past decade "obtained a rising share of an educational budget that has itself been taking a rising share" of public expenditure and of the national income as well. But he

has his eyes on the cost of the operation, and is anxious to encourage current studies of such questions as the cost of educating students in universities of different kinds and sizes and the productivity of staff. He seems to be moderately cheered by the studies recently embarked on under the Committee of Vice-Chancellors and Principals of the use of plant and facilities at universities. On the pattern for rationalizing the distribution of effort of the universities, he considers it right that, taking the nation as a whole, the University Grants Committee should work through the subject panels which it has established. There may also be a case for looking at the availability of resources in higher education (in all its forms) on a regional basis as well. Several of the regional planning councils, which have strong representation from higher education, are already doing this.

The balance between the universities and the other institutions at which higher education is provided has been a bone of contention for some time, and particularly since the British Government took steps to formalize the development of the polytechnics. Mr. Crosland points out that this is not an innovation, but an attempt to make the best of a plural system which already exists. He argues that there is a "separate social demand" for a plurality of institutions of higher education. For one thing, polytechnics can provide higher education, on a part-time basis, for people already in employment. For another, they can provide degree courses oriented towards industry which more orthodox universities might be hard-pressed to provide. Mr. Crosland does not fear that the parallel development of universities and polytechnics will create an excess capacity for higher education. Rather, he seems fatalistically convinced that the rising demand for higher education will use up whatever capacity there may be created.

# Volcanic Rings on the Moon

by  
G. FIELDER

University of London Observatory,  
Mill Hill Park, London, N.W.7

Are the low ring structures on the Moon older than the craters? A study of the Flamsteed *P* ring structure revealed by photographs taken by the U.S. lunar probes *Orbiter I* and *Surveyor I* throws new light on this question.

It is generally assumed that lunar rings such as Stadium (diameter 65 km) and Daguerre (44 km) are old features because, it is argued, they have been eroded to mere remnants of former grand ring structures like Copernicus. Elsewhere I have listed evidence<sup>1</sup> which points strongly to such "elementary rings" being among the most youthful of volcanic forms on the Moon's surface. I shall not repeat the evidence here: it led to an evolutionary concept of the origin and anagenesis of elementary rings which can be summarized as follows:

Ring fracturing of the lunar crust is followed by the intrusion of lava sheets. Lava is extruded at those points around the circumference of a ring structure where the

local hydrostatic conditions are favourable and the lava flows across the surface for distances of several kilometres. Some volcanic cratering (collapse pits, especially) also occurs mainly in annuli defined by the sub-parallel ring fractures. The floor of the principal ring structure subsides and forces lava to issue from fissures and rim volcanoes (cones and calderas), thus building up the low ringwalls by successive flows. In general, the inner rings of a given ring structure develop later than the outer ones.

At the time this theory was published, I knew of no support for the idea. Now, however, *Orbiter I* has produced exceptionally clear photographs of the large elementary ring Flamsteed *P*; and Dr. J. A. O'Keefe, R. G.

Fig. 1. The north-east rim of Flamsteed *P* as recorded by *Orbiter I*. Lava flows have formed mountains and the lower wrinkle ridges. Total width about 56 km. (N.A.S.A. photographs.)

Fig. 2. Chart prepared by the Aeronautical Chart and Information Center, U.S. Air Force, showing the whole of Flamsteed P. The Surveyor I landing site is indicated (arrow); it is near to the mountains Flamsteed  $\theta$  and  $\beta$  shown in greater detail in Fig. 1. The squares have a side of 15 km.

Strom and E. A. Whitaker have independently drawn my attention to certain features of the photographs which appear to uphold the theory. The aim of this article is to examine and interpret some of the more revealing details on two recent N.A.S.A. *Orbiter* photographs.

The *Orbiter* I photographs L-66-7828 and 7843 each cover an area of about 32 by 39 km in Oceanus Procellarum. The areas overlap, and the photographs are reproduced in Fig. 1 as a mosaic. It is seen that the bright mountains in Fig. 1 form a broken arc, and that a prominent wrinkle ridge parallels the arc. The arc is in fact the north-east (astronautical convention) portion of the rim of a subcircular ring known as Flamsteed P

(Fig. 2). The highest of the prominent group of mountains in the upper part of Fig. 1 has been designated Flamsteed  $\theta$  and the most massive mountain in the lower part of Fig. 1 has been named Flamsteed  $\beta$  (Fig. 2). The profile of the upper parts of Flamsteed  $\theta$  (Fig. 3) was recorded earlier by Surveyor I, some 20 km away. Flamsteed P is 100 km in diameter; thus Fig. 1, which has a resolution in some places better than 10 m, shows part of the rim of a very large lunar ring formation.

The rim consists of discontinuous mountains and hills which have mean slopes of  $10^{\circ}$ – $25^{\circ}$  and altitudes of up to about 600 m (Fig. 2). Although there is a tendency for individual mountains to assume the form of rounded, dome shaped units characteristic of fluids which were once viscous, the overriding linear form of each block of eminences suggests that they are controlled by fractures.

Of paramount importance is the fact that details on the flanks of these eminences may be interpreted in terms of features essentially similar to those known in volcanic regions of the Earth. Special reference should be made to Figs. 4 and 5 in which the following details of Flamsteed  $\theta$  and  $\beta$  can be observed. First, several of the mountains terminate with a steep pedal slope, 50–100 m in horizontal extent, measuring  $\lesssim 25^{\circ}$ . At the top of this slope the terrain levels out somewhat to form an apron 200 m wide before hummocky material is encountered, when the general slope steepens again for 500–800 m. Here, however, the terrain is so crenulated that slope reversals occur with a wavelength of about 100 m. Most of the raised crenations are sub-parallel to the steep border that abuts on the lunabase. They assume the form of lenticles some 200 m long or define lobes that are reminiscent of the flow ridges in a lava field. For example, this distinctive appearance may be seen in a flow of intermediate lava from a Chilean volcano described by Guest<sup>2</sup> (Fig. 6).

The apron material is smoother than the hummocky material, but the former does carry crenations even though they are of smaller amplitude and wavelength than in the hummocky material. Individual hummocks, or blocks of rock, as small as 10 m across can be clearly identified on the hummocky flows under conditions of very low lighting. The two materials may be structurally or chemically different, but both are characteristic of lava.

The lava front is perhaps 20–40 m high where the apron terminates and the frontal profile is such that it cannot

Fig. 3. The upper part of the mountain Flamsteed  $\theta$  as recorded by Surveyor I. (U.S. Information Service.)

Fig. 4. Flamsteed  $\theta$  and environs, enlarged from Fig. 1, showing lobate termini of several lava flows. Total area shown about 28 km  $\times$  20 km. (N.A.S.A. photograph.)

be composed of erosional detritus, which would wedge or sliver to an unresolvable thickness. The individual fronts in the hummocky material are perhaps 15 m high. It is clear that viscous materials were involved in both cases.

It would appear that the apron was produced by a lava flow which was followed by several superincumbent flows of highly viscous lava. The later lavas issued from fissures or vents, some of which may be seen in the *Orbiter* I pictures. A lunar lava flow, however, would

de-gas rapidly and produce a very porous, indurated rock froth close to the surface. This frothy layer would be an excellent thermal insulator, and hot liquid lava would continue to flow underneath it and pucker or heap it into flow ridges. Thus the steepness of the lava fronts would be an indication of the viscosity and strength of the outgassed materials rather than of the original lavas.

Because the mechanism of coacervation of lava takes an extreme form, on the Moon, the observed shortness of the flows and the slopes of the lava fronts are to be expected even if the original lavas were of a type that would have produced longer flows with lava channels under terrestrial conditions.

Some craters can be observed in both the apron materials and the hummocky flows, but these craters are few in comparison with the numbers observed in equal areas of the surrounding terrain. Both the apron and the hummocky flows are of relatively bright, lunaritic material. These flows can be grouped together and referred to as the lunaritic lava flows. The adjacent terrain is of darker mare-type material and will be referred to as lunabase.

At least four of the largest craters in the lunaritic flows are conical or dimple craters, which suggests collapse following the withdrawal of lava. Other craters tend to collect along the saddles formed by the adjacent mountains, so it is improbable that these craters are impact craters.

Along a total of 180 km of lunaritic lava fronts, and over 60 km of wrinkle-ridge lava fronts (Figs. 4 and 5) that are clearly associated with the ring-fracturing of Flamsteed  $P$ , there are sixteen probable cases of craters which have been overlapped by the lava flows, one certain case of a 1 km ghost ring which has been overlapped, and two cases of craters which have apparently been distorted by the flow of lava. On the other hand, seven craters bite into the lava fronts, and a few partial rings also intrude into the lunaritic flows. One partial ring, 1,100 m in diameter, intrudes into a well defined hummocky flow and downfaults it. This is evident from the mutual relation of the flow lines or ridges and the wall of the ring. The ring itself is probably a caldera because its level floor is bordered by an arcuate chain of craters which may well be the locus of one of the fractures along which subsidence proceeded and from which gas-charged lavas were extruded.

Fig. 5. Flamsteed  $\beta$ , enlarged from Fig. 1, showing flow ridging and steep terminal slope of lavas. Total area shown about 9 km  $\times$  12 km. (N.A.S.A. photograph.)

Fig. 6. Flow ridging of a viscous, intermediate lava in Chile. Characteristics of this flow are the same as those applying to the lunar lavas. Total area shown about 13 km  $\times$  10 km. (After J. E. Guest.)

Many of the plentiful eumorphic craters in the lunabase around the lunaritic lava flows are without raised rims; stereoscopic views indicate that they are pits in the ground. It is also possible that they are small calderas of collapse. Others, with rims, may be impact craters.

The relation between the lunaritic lavas, the materials of the lunabase, and the craters and rings shows that some craters and rings were formed before the peripheral lava flows of Flamsteed *P* and other craters and rings were formed later. The counts may be too few to be of great significance, but it appears that twice as many craters and rings were formed in the lunabase before the apron lavas were extruded as after they had solidified. The relative paucity of craters in the lunaritic lavas adds to the foregoing observations to suggest that the lunaritic lavas are in general more recent than the surrounding lunabase. The steep terminal slope and the apron lavas, however, are not always present; in places where these features are absent, the hummocky lavas extend down to, and seem to dip under, the lunabase. Thus it is plausible that lavas of both the lunarite and the lunabase were coeval, one sometimes flowing over the other; it therefore appears that counts of craters do not offer sufficiently reliable data on which to base the dating of the different lava flows. Indeed, it seems that the lunarite carried fewer craters than an equal area of contemporaneous

lunabase and, thus, that the majority of craters are not of impact origin.

This premise about the small craters must await confirmation, but the conclusion that the ringwall of Flamsteed *P* is a youthful volcanic feature is inescapable. Similar evidence that the walls of lunar ring structures and isolated ridges and domes are volcanic extrusives can be found on many of the *Orbiter* photographs. For the first time, the slopes of dome shaped hills are seen to preserve concentric ridging characteristic of flow ridging.

These results demolish the long held hypothesis that all low "elementary rings" on the Moon are old worn-down impact craters. They answer Marcus's<sup>3</sup> criticism of an argument I used to support the volcanic hypothesis. They imply a source of heat for comparatively recent lunar volcanism.

I am most grateful to Dr. J. A. O'Keefe, R. G. Strom, and E. A. Whitaker, all of whom drew my attention to the presence of lava flows around Flamsteed *P* before I had seen the pictures, and I thank the U.S. National Aeronautics and Space Administration for providing the *Orbiter* photographs. I also thank J. E. Guest for useful discussions on lava flows.

THE Carbohydrate Discussion Group (a Chemical Society Subject Group) is to hold a meeting in the University of Bristol during April 7-8. Further information can be obtained from Dr. R. D. Guthrie, The Chemical Laboratory, The University of Sussex, Falmer, Brighton, Sussex.

A CONFERENCE on "Molecular Sieves", organized by the Society of Chemical Industry, is to be held in London during April 4-6. Further information can be obtained from the Honorary Secretary, Conference on Molecular Sieves, Society of Chemical Industry, 14 Belgrave Square, London, S.W.1.

THE ninth international conference of the Society for Biological Rhythm is to be held in Wiesbaden during April 6-8. Further information can be obtained from Professor Werner Menzel, Amalie-Sieveling-Krankenhaus,

Farmsener Landstrasse 73, Hamburg-Volksdorf, West Germany.

A SYMPOSIUM on "Biomechanics", sponsored jointly by the Rock Island Arsenal, Army Weapons Command, Army Research Office-Durham and Augustana College, is to be held on the Augustana College campus during April 5-6. Further information can be obtained from RIA Biomechanics Symposium 1967, c/o Professor J. E. Ekblad, Augustana College, Rock Island, Illinois.

A THREE day symposium on "The Ocean from Space", sponsored by the American Society for Oceanography and the Gulf Universities Research Corporation, is to be held in Houston, Texas, during April 5-7. Further information can be obtained from "The Ocean in Space", American Society for Oceanography, P.O. Box 53600, Houston, Texas.

## BOOK REVIEWS

## SCIENCE AND CRAFT

## Les Mécaniques de Galilée

Traduites de l'Italien par le P. Marin Mersenne. Edition critique par Bernard Rochot. (Le Mouvement des Idées au XVII<sup>e</sup> Siècle, 4.) Pp. 80. (Paris: Presses Universitaires de France, 1966.) 10 francs.

La Vie Domestique dans le Mâconnais Rural Préindustriel Par Susanne Tardieu. (Université de Paris. Travaux et Mémoires de l'Institut d'Ethnologie, Tome 69.) Pp. 525. (Paris: Institut d'Ethnologie, 1964.) 120 francs.

ENGLISH readers have a modern translation of this work of Galileo's published by Stillman Drake in 1960. *Le Meccaniche*, composed about 1600 for the benefit of Galileo's pupils at Padua, was only printed during his lifetime in this French version (it is not a straight translation) by Mersenne. Several manuscript copies of the original are known; one had come into Mersenne's hands by 1629. This little book is not to be numbered among Galileo's major creations, for it is after all no more than his version of the "treatise on the five simple machines" that had descended from the pseudo-Aristotelian *Mechanica*. Like everything Galileo wrote, it contained interesting touches; but it does not contain his discoveries in mechanics.

In 1629, although Galileo was world famous as an astronomer and controversialist, his fruitful studies in mechanics were known only to few intimate friends, although they were (probably) virtually completed by 1609. By 1634, when this little book of Mersenne's appeared, the position had changed doubly: since his trial and abjuration in the previous year Galileo had become a hero to some, a heresiarch to others, while the cause of this trouble, the *Dialogue on the Two Chief Systems of the World*, had also revealed his new mechanical notions for the first time.

It seems to have been the intention of Marin Mersenne, a great admirer of Galileo despite his holy orders, both to add distinction to the Italian's name and to make his work in mechanics better known in France, though indeed, in the present book, he could do little enough in the latter respect. Hence he was to take up this same task again, in *Les Nouvelles Pensées de Galilée* (1639).

The main historical interest of the little book here re-issued revolves around the "translator" rather than the original author. It was significant in introducing Galileo to a wider circle of Frenchmen, and for its clear expression, by Mersenne himself, of important mechanical principles. Nevertheless, it must be said that this role was both limited and local.

In her capacious volume, Mlle Tardieu, *chef de service* at the Musée des Arts et Traditions Populaires in Paris, gives the full scholarly treatment to her subject: the household equipment, and the daily life in which it figured, of the Mâconnais region in south central France—a vine-growing region the best known growth of which is Pouilly Fuissé, verging on the Beaujolais country to the south—before it was much affected by modern industrialization, that is roughly before 1900. Mlle Tardieu's scholarship does nothing to detract from the fascination of her material, compiled partly from objects in museums or still in use, partly from the recollections of aged villagers, and partly from notarial inventories of household goods. The point of the enquiry is, of course, that life

in this quiet, poor region (of whose place-names the *Oxford Atlas* lists only the towns of Mâcon and Cluny) changed little from the seventeenth century to within living memory; changes in detail occurred—the replacement of resin tapers by tin lamps fed first with rape-oil, then kerosene—and perhaps there was some slight secular increase in comfort, but basically the same harsh structure of peasant village life continued. The domestic interior remained barely furnished, even though earthenware partially supplanted pewter, unremitting toil in the fields went on with the same beasts and the same tools. The Mâconnais has declined in population since the end of the eighteenth century; if any one still wonders why all people at all ages have fled from country to town when they could, they might reflect on the winter "veillées" of the Mâconnais, where the fuelless families gathered turn by turn in each other's cowsheds, each family in turn providing the glimmer by which the women span. The reason for sitting together in the cowshed was to join the warmth of human bodies as closely packed as might be with that of the animals, and that of their dung left to heat by putrefaction. The same people were sometimes forced to set the bread-dough to rise in their beds, employing the same resource to keep the noon soup hot for supper.

In Britain we are historically more familiar with the social problems of industrialization: the factory, mine and slum. This book describes, with great wealth of solid information but without either romance or pathos, the reality of the "old world" which must be measured against the horrors of progress: a world in which, for the village, conscription might be a family tragedy, phylloxera a demographic disaster.

A. RUPERT HALL

## ABBE AND AFTER

## The Theory of the Microscope

By L. C. Martin. Pp. xiv+488. (London and Glasgow: Blackie and Son, Ltd., 1966.) 100s. net.

It is very nearly a hundred years since Abbe formulated his diffraction theory of image formation. That hundred years has seen some tremendous advances in practical microscopy and other branches of optics. The best microscope objectives are not far short of practical perfection; new methods such as phase contrast and interference microscopy are commonplace and the development of lasers and holography offers exciting possibilities of further progress. It would be wrong to say that theory has lagged behind, but it is some measure of the complexity of the subject that this is the first comprehensive attempt to deal with the problem from the standpoint of modern wave optics.

The microscope is only an optical instrument, after all, but it is exceptional in that it uses lenses of unusually high aperture and is very much concerned with achieving the ultimate in resolving power. These peculiarities lead to problems not often encountered in other optical instruments, some of which are still unsolved. The first three chapters of this book are, in fact, a very useful introduction to diffraction theory and wave optics. The remaining five chapters deal with image formation with incoherent illumination, the theory of relative coherence, image formation with coherent illumination, the microscopy of phase objects and image formation in cases of partial coherence. There are several mathematical appendixes, including a useful one on Fourier series, integrals and transforms.

Abbe's work served to emphasize the importance of diffraction in image formation, but the narrow conservatism of some of his followers led to a long period of acrimonious discussion, much of it recorded in the *Journal of the Royal Microscopical Society*. Today, the development of partial coherence theory and the better

appreciation of the physical processes underlying image formation render such arguments sterile. Unfortunately, this does not seem to have penetrated to all writers of text-books on microscopy, and one often finds a good deal of heat generated on the relative merits of Köhler and "critical" illumination, on the reasons for using highly corrected condensers and on the exact limits of resolution. Professor Martin's book discusses such matters and many more. It is a considerable achievement to have covered so much ground while striking a nice balance between mathematics and physical principles. To have done so after official retirement is little short of amazing.

R. BARER

## ELECTRON MICROSCOPY

### Introduction to Electron Microscopy

By Cecil E. Hall. Second edition. (International Series in Pure and Applied Physics.) Pp. ix + 397. (New York: McGraw-Hill Book Company, Inc.; Maidenhead: McGraw-Hill Publishing Company, Ltd., 1966.) 140s.

It is unusual to find a second edition of a book concerned with applied physics which is shorter than the original. When the subject is electron microscopy, it is little short of astonishing. As the author says in the opening sentence of his preface, the rate of advance has been rapid since the first edition appeared in 1953. Yet he has been able to cut the text by more than 50 pages, while including a certain amount of new material.

It is questionable whether his efforts have been altogether successful. Some of the matter excluded, chiefly descriptions of commercial models of electron microscopes and of particular applications, could well have been retained if only to give the reader a clearer view of what the finished instrument is like and of its power as a research tool. On the other hand, the positive revision of the text has been much less thorough than is suggested by the blurb. The main body of the text, in fact, remains unchanged although a certain amount of re-arrangement has been done, such as the transfer of the historical survey from Chapter 8 to the opening chapter where it properly belongs. The "considerable revision" of Chapters 8 and 9 comes down to the addition of a few paragraphs on electron scattering, on measurements of Fresnel fringes and on television display systems. Chapter 10, on "Techniques and Applications", has necessarily received greater revision.

From the point of view of microscopy as at present practised, there is inadequate treatment of anti-contamination devices, photographic emulsions for electrons and the examination of metal films. In respect of current research with a bearing on the future of electron microscopy, there is only a bare mention of quadrupole lenses and of energy analysis of the imaging beam, and none of Riecke and Ruska's new type of objective lens. The section on high voltage microscopes has now been omitted, in spite of the striking work going on in France and Japan. In general, recent work in France and Germany is little mentioned; the names of Castaing and Möllenstedt do not appear in the author index.

That said, it remains true that this is the best text-book on the subject we have. It was originally, and still is, based on a one-term course given in the Biophysics Department of M.I.T. As such, it is rightly concerned with fundamentals and not with a complete presentation of the state of the art. To do the latter now calls for the combined efforts of a team of specialists in its various branches, as for the recent French work in two volumes, *Traité de Microscopie Électronique*. Taken together with the books listed in his appendix, Professor Hall's text will continue to serve as the recommended introduction for research students and others new to electron microscopy.

V. E. COSSLETT

## REINVASION OF CANADA

### Evolution of Canada's Flora

Edited by Roy L. Taylor and R. A. Ludwig. Pp. viii + 137. (Toronto: University of Toronto Press; London: Oxford University Press, 1966.) 44s. net.

THE Founding Meeting of the Canadian Botanical Association held in Ottawa in 1965 developed the scientific theme of the evolution of the flora of Canada, and this volume is a symposium of the chief papers presented. Since the Tertiary uplift of the Rocky Mountains system, Canada has undergone a sequence of glaciations of great extent and severity. Very little trace remains of the effect of pre-glacial or even interglacial conditions and the whole of the existing fauna and flora is the consequence of migration and re-establishment since the maximum of the Wisconsin glaciation about 20,000 years ago. Canadian botanists have begun to exploit the essential tools for reaching objective conclusions on the Quaternary history of their vegetation—radiocarbon dating, palynology, the identification of macroscopic plant remains, the applications of genetic analysis and the detailed study of patterns of distribution. This symposium reflects the progress made by the use of these methods since the pioneering research into biogeography by Marie-Victorin and Fernald early in this century. Contributions on algal zonation on the Pacific coast and on the nature of vegetational propagation have only a marginal link with the main theme of the volume, but are very interesting in themselves. Those contributions which lie in fields of current scientific activity are of a high standard and great interest. One or two others concern themselves less rewardingly with consideration of general concepts. The general unevenness is a consequence of the sparsity of botanical scientists in so vast a territory as Canada, but the symposium affords very welcome evidence of activity and advance towards biogeographic studies which will be of great importance not only to botany but to associated disciplines of archaeology, geology and climatology.

H. GODWIN

## ADVANCING BOTANY

### Advances in Botanical Research

Vol. 2. Edited by R. D. Preston. Pp. xii + 382. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1965.) 75s.

THIS second volume of *Advances in Botanical Research* contains six articles by leading authorities in their respective fields, which include the phyletic implications of flagellar structure (I. Manton), numerical taxonomy (W. T. Williams and M. M. Dale), the ultrastructure of the wall in growing cells (P. A. Roelofsen), cell wall protein (D. T. A. Lamport), embryology (P. Maheshwari and N. S. Rangaswamy) and soft rot fungi (J. Levy).

In his introduction to the first volume, the editor explained that the authors had been invited to express opinions freely and "to speculate as widely as they dare". The articles, therefore, differ in character from the somewhat colourless catalogues so frequently encountered in review journals, and we have lively and stimulating accounts, in which the personalities and viewpoints of the authors come through clearly.

With so wide a range of specialisms, it would be presumptuous to comment in detail on the particular articles. But, judged from the standpoint of the non-specialist reader who wishes to bring his reading up to date in fields outside his own specialism, the articles differ considerably in intelligibility and in interest to the general reader; some, such as the articles on cell wall ultrastructure, embryology and soft rot fungi, can be followed easily and profitably by the non-specialist, whereas others are too difficult or too specialized and are primarily of value to

the research worker in the particular areas covered. Thus, one is led to ask, first, for whom is this type of book intended and, second, does it fill a special need not already met by existing journals? The answer to the second question would seem to be that there are certain areas of botanical research not covered by specialist review journals, and that there is therefore a place for this series, with its very wide coverage. But the very breadth of the series creates its own problem, since it is unlikely that the reader will find more than one article in each volume lying within his own field, as compared with a review journal devoted to a particular branch of botany. Consequently, if this series is to serve more than a small band of specialists, most of the articles will also have to be intelligible to the non-specialist reader who wishes to read further within, or outside, his own branch of botany, and the subjects will have to be chosen for their appeal to a reasonably wide audience.

This plea for a little more consideration for the non-specialist reader should not obscure the fact that all the papers in this volume are of a very high quality and that it can confidently be recommended as a valuable contribution to current botanical thought.

P. F. WAREING

## MOLECULAR PARASITOLOGY

### Biochemistry of Parasites

By Theodor von Brand. Pp. ix+429. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) 128s.

THIS book is not simply a revision of the previous edition (1952), entitled *Chemical Physiology of Endoparasitic Animals*, for it has been rewritten with the shift of emphasis indicated by the new title. By combining all aspects of biochemical structure and function of each chemical class into a single chapter, the number of chapters has been reduced from twenty to nine. As well as three chapters devoted to carbohydrates, there are separate chapters on inorganic substances, lipids, proteins, nucleic acids, vitamins and respiration. The inclusion of nucleic acids indicates the advances in this field since 1952, while the chapter in the first edition entitled "Miscellaneous Physiologically Active Substances" becomes the basis of the present chapter on "Vitamins". Much information of a physiological nature, such as osmotic relationships and endocrinology, has been omitted from the present volume. The dispersal of information previously contained in the section "The Biochemical Basis of Chemotherapy" may be a mistake, for such a chapter would be more in line with the compact style of the current edition.

Inevitably, because of the rapid accumulation of knowledge in recent years, the size of the book has increased by almost ninety pages, even though much early work has been omitted where superseded by more recent investigations. The biochemistry of the host-parasite relationship is well dealt with in the new volume, but each topic is included in the appropriate chapter and does not form a separate section as before.

Dr. von Brand's personal experience in much of the work has enabled him to extend the usefulness of the biochemical evidence by pertinent references to related work in the fields of histochemistry, cytochemistry and electron microscopy. There are also many practical tips, such as the use of enzymes for glucose estimation (p. 46) and criteria for the inhibition of enzymes by drug action (p. 177). The book is almost overflowing with well documented facts, and relevant data have usually been condensed into useful tables. Even so, the addition of a short section at the end of each chapter, or even of a separate chapter, discussing biochemical adaptations to a parasitic existence would have provided a better insight

into these important problems of parasitology. The strict separation of chapters sometimes prevents a continuous discussion of biochemical specialization in one parasitic group—oxidative metabolism in the trypanosomes, for example. In its present form the book is therefore of greater use to the experienced research worker than the young student.

A survey as extensive as this also serves as a comment on the present state of biochemical parasitology. It indicates that most of the work has been carried out on a small number of organisms, chiefly malaria parasites, trypanosomes, trichomonads, cestodes and nematodes. Three chapters devoted to carbohydrate biochemistry also indicate the unevenness of the development of metabolic studies on parasites. Dr. von Brand can report little advanced work on the biosynthesis of macromolecules, which occupies the attention of biochemists in other fields. Such studies have been hampered by the difficulties of parasite isolation and maintenance, but the problems are not insurmountable.

In conclusion one can say that this is the only recent book which deals adequately with the biochemistry of all groups of parasitic animals. No errors of fact are to be found in the text, and the index, although not especially exhaustive, is generally adequate.

C. D. GINGER

## MICRO-ORGANISMS TO ORDER

### Theoretical and Methodological Basis of Continuous Culture of Micro-organisms

Edited by Ivan Málek and Z. Fencel. Translated by J. Liebster. Pp. 655. (Prague: Publishing House of the Czechoslovak Academy of Sciences; New York and London: Academic Press, 1966.) 208s.

THIS book is really a series of critical essays on many aspects of the continuous culture of micro-organisms. Inevitably there is some overlap between them. The range covered is wide and, indeed, in the introduction Academician Málek writes: "It is the aim of this monograph to lay firm foundations for the wide application of the continuous cultivation method in microbiological, biochemical, genetic and cytological research and a basis for progress of the fermentation industries". This it does admirably.

Málek prepares the way for his colleagues and also gives a historical account of the development of continuous processes including multi-stage systems. He then looks to the future. J. Řířica deals with the various techniques in considerable detail and K. Beran discusses their application to many problems in pure and applied research. Z. Fencel analyses fully the underlying mathematical theory, while M. Burger focuses his attention on the occurrence of mutations in chemostat systems. Pathogenic organisms are also dealt with and the advantages of continuous cultivation, not only for the production of vaccines, etc., but also in fundamental studies, are pointed out (A. Stejskal). Techniques suitable for the growth of algae and animal cells and for use in soil microbiology are next examined (R. Řetovský, M. Pospíšil, J. Macura). Finally, J. Hospodka considers industrial applications in detail.

The book contains a wealth of practical details pertinent to the construction and operation of suitable apparatus and a very comprehensive bibliography. The translation is adequate, but the legends for Figs. 5.2-1 and 5.2-3 have been interchanged and there are some typographical errors in Fencel's equations. (A list of corrections has been issued but is not, unfortunately, distributed with the book.) Although the price is high, this work should prove invaluable to anyone engaged in the study and the application of continuous processes either in the laboratory or in industry.

A. C. R. DEAN

## ECOLOGY OF MICRO-ORGANISMS

### Principles of Microbial Ecology

By Thomas D. Brock. (Prentice-Hall Biological Science Series.) Pp. xiv + 306. (Englewood Cliffs, N.J.: Prentice-Hall, Inc.; London: Prentice-Hall International, 1966.) 62s.

NOT long ago, inclusion of the word "ecology" in the title of a microbiological research project was a sure way of diverting prospective research students elsewhere. Today the situation is more cheerful and Professor Brock's book should help to dispel the notion that the subject is a dull one. As the first book of its kind, it will be informative for the younger graduate not yet committed to a particular field of research as well as for the larger audience of microbiologists, sanitary engineers, pedologists, petroleum engineers, geochemists, physicians, food sanitarians and limnologists for which it is intended.

In the first three chapters, amounting to about one-third of the text proper, Professor Brock lays the basis for the physiological and biochemical approach to the examination of the behaviour of micro-organisms in natural situations. The experienced microbial physiologist will find much that is familiar to him here. Fragmentation of some sections seems excessive—Chapter 3, on "The Ecology of the Cell", has no fewer than 43 subheadings in 57 pages.

In the remainder of the book Professor Brock sets about the integration of a diversity of information from a variety of fields and the enunciation of principles. He deals with dispersal, population ecology, interactions between microbial populations, microbial ecosystems, interactions of micro-organisms with macro-organisms and microbes in macro-ecology. Sometimes the principles remain elusive and the text becomes reminiscent of a textbook in soil microbiology or chemistry, plant pathology or medical microbiology among others. In my opinion the coverage is too wide but, to be fair, Professor Brock states clearly in his preface that he is attempting to provide a picture of the place of micro-organisms in nature and human society. He has collected and documented much information in a compact and not too expensive space. All credit is due to him for providing a welcome first text on microbial ecology. J. W. HORTON

**Biographical Memoirs of Fellows of the Royal Society**  
Vol. 12. Pp. 564 + 28 plates. (London: The Royal Society, 1966.) 100s.; \$15.

THERE is much interest and useful information in the twenty-eight short biographies contained in this volume. The more famous fellows include Sir Winston Churchill, E. V. Appleton, J. B. S. Haldane and Lord Nuffield, but perhaps the more interesting are the other less well known scientists. Theodore von Kármán was a mathematical prodigy who became a brilliant mechanical and aeronautical engineer. During the First World War he helped to develop the first stable hovering helicopter. He was later a member of the committee appointed to investigate the Akron and Macon dirigible disasters, and was a consultant on the Grand Coulee Dam Project. He was an early supporter of the science of astronautics, when other scientists still classed it as science fiction; von Kármán preferred enthusiasts with imagination to serious scientists without imagination. Hans Pettersson, another foreign member, was the Swedish oceanographer who organized the voyage of the research ship *Albatross*, during which measurements of light absorption and radioactivity as well as biological investigations of the sea were carried out.

Some of these fellows of the Royal Society had strong non-scientific interests. T. G. Brown was a neurophysiologist who climbed Mont Blanc; the Canadian physicist, J. S. Foster, who was involved in the development of radar, drew up plans for a concert hall at McGill University, and R. G. Hatton, who was for thirty years the director of the East Malling Research Station, founded the Kentish branch of the Workers' Educational Association. This volume is full of such fascinating facts; it makes interesting reading and a useful reference book.

MARY LINDLEY

### Early Public Libraries

**A History of Public Libraries in Great Britain Before 1850.** By Thomas Kelly. Pp. 281. (London: The Library Association, 1966.) 56s. (L.A. members, 42s.)

ONCE again Dr. Kelly has demonstrated the compatibility of erudition and lucidity of exposition. Though thoroughly documented, this book will be read with ease by the general reader as well as the scholar, and it has some features of particular interest to a scientist. It notes the relation between the growth of libraries and public interest in science, and the book is welcome for its emphasis on the feature which made Chetham's Library, Manchester, of outstanding importance—provision of adequate income for the purchase of books. Even today, the University Grants Committee, much less the Department of Education and Science, has failed to appreciate the significance of this simple truth for either the new or the old university libraries. Dr. Kelly's book is also of importance as a corrective to the report of the Select Committee on Public Libraries of 1849, which has attracted some attention in recent years, following the centenary of the Public Libraries Act. There is a pertinent reference, in connexion with the origins of the British Museum Library, to Bacon's "Solomon's House" and the utterly inadequate provision for libraries in London in the seventeenth century is duly noted. Primarily a book for the scholar, it will be read with care by anyone interested in social history and particularly in education, whether scientific or technical or general. R. BRIGHTMAN

### Flora of the U.S.S.R.

Vol. 12: Leguminosae: Astragalus. Chief editor V. L. Komarov. Compiled by A. G. Borisova, N. F. Goncharov, S. G. Gorshkova, M. G. Popov and I. T. Vasil'chenko. Edited by B. K. Shishkin. Translated from the Russian by N. Landau. Pp. xxviii + 681. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1965.) 182s.

THERE are numerous important revisions in the monumental *Flora of the U.S.S.R.*, edited by Academician V. L. Komarov, but the fact that they were originally written in the Russian language has often been a barrier to non-Russian botanists who wished to consult them. The present English translation is of Volume 12 of this great flora, devoted entirely to the single genus *Astragalus* (Leguminosae).

The great size and complexity of *Astragalus*, which has not been generally revised for the old world since Bunge's work, *Generis Astragali Species Gerontogaeae*, was published in 1868–70, make the present account of great taxonomic importance to any serious student of the genus. The degree of importance is indicated by the fact that, although many of the 103 sections here admitted were delimited by Bunge, no less than twenty-two were established in recent years by N. F. Goncharov, who wrote much of the present work but died before it was quite complete; and also that no less than 302 of the 849 species included were described as new by Russian botanists since 1930. As the preface states, this very large number "does not nearly exhaust the wealth of species of this genus, the greatest in our flora". It is noteworthy that very few infraspecific taxa are recognized and,

presumably as a matter of deliberate taxonomic policy, no sub-species.

The greater part of the genus was revised by Goncharov, a lesser but nevertheless important part by A. G. Borisova, and other smaller portions by other authors.

The translation by Dr. N. Landau appears to be efficient and clear, and his undaunted perseverance in ploughing through so many specific descriptions, mostly not written in a particularly enlivening style, is praiseworthy.

J. P. M. BRENNAN

**The Biochemical Genetics of Vertebrates Except Man**  
By I. E. Lush. (North-Holland Research Monographs. *Frontiers of Biology*, Vol. 3.) Pp. viii + 118. (Amsterdam: North-Holland Publishing Company, 1966.) 36s.

THIS monograph, the third in the series "Frontiers of Biology", is devoted to a tabulation of the biochemical variations uncovered so far in mammals, birds and fishes. The author has assembled a large quantity of material, and made interesting reading out of a text which, from its necessary form of presentation, might have been tedious. The subjects discussed in some detail include genetic variations in transferrin, haemoglobin,  $\gamma$ -globulin, esterase, amylase, lactate dehydrogenase and pyrimidine catabolism, to name only a few. This is the first time that an attempt has been made to collect and summarize this material from a widely scattered literature. The concluding chapter includes a clear concise treatise on deletion and duplication in vertebrate biochemical genetics, and the quaternary structure of proteins.

The treatment on the whole is descriptive rather than analytical. One of the most dynamic sciences at the moment is the investigation of the chemical nature and behaviour of the hereditary unit. This publication will serve as a convenient source of reference, not only to biochemists and geneticists interested in this field, but to all researchers who are just awakening to the realization of the powerful research tool and the potentialities afforded by biochemical variants.

H. M. MURPHY

### Radioactive Pharmaceuticals

Edited by Gould A. Andrews, Ralph M. Kniseley, and Henry N. Wagner, jun. (Proceedings of a Symposium held at the Oak Ridge Institute of Nuclear Studies, November 1-4, 1965.) (U.S. Atomic Energy Commission/Division of Technical Information.) Pp. viii + 728. (Springfield, Virginia: Clearinghouse for Federal Scientific and Technical Information, N.B.S., U.S. Department of Commerce, 1966.) \$5.

THE publication of these proceedings comes at a time of particularly rapid growth of the use of radioactive materials in medicine. The purpose of the symposium was to summarize and correlate the recent advances in the development of radioactive pharmaceuticals for use in clinical medicine and biological research. It succeeds admirably. The symposium title *Radioactive Pharmaceuticals* itself acknowledges the technical advances and the change of status which have occurred in the 28 years since thyroid function was first demonstrated with radioactive iodine. To some extent it may also mislead, since a radioactive pharmaceutical is usually administered to provide information, commonly of organ function, rather than to elicit a specific pharmacological response. The papers in these proceedings are accordingly largely devoted to the discussion of radioactive materials used in diagnosis: their production, their characteristics and the techniques for using them. Their applications in radiotherapy are not included.

Recently developed radiopharmaceuticals figure prominently and provide a convincing illustration of the more sophisticated diagnostic techniques now being achieved. The instrumental aspects are not reported in the proceed-

ings though the consequences of concurrent developments in equipment for external body scanning are everywhere apparent.

The forty papers range widely through biochemistry, pharmacology, radionuclide production, nuclear medicine and the radiopharmaceutical industry. The more critical outlook of both suppliers and users of radioactive pharmaceuticals is reflected in the number of papers concerned with quality control and licensing regulations.

The proceedings provide not only a record of what was a well timed and eminently successful symposium, but a valuable reference for all whose work brings them into contact with nuclear medicine.

C. C. EVANS

### Strong Solids

By A. Kelly. (Monographs on the Physics and Chemistry of Materials.) Pp. xv + 212. (Oxford: Clarendon Press; London: Oxford University Press, 1966.) 42s. net.

DR. KELLY has written a book quite unlike any other at present available. He has undertaken a single-minded treatment of a central question: what determines the ideal strength of solids, and what steps can be taken to approach this in practice as nearly as possible.

The first chapter shows how the ideal fracture and shear strengths can be calculated, and what physical parameters must be controlled to maximize them. Next, Dr. Kelly summarizes the fracture promoting properties of cracks, and goes on to expound very selectively some relevant properties of dislocations, in particular the forces binding them to the lattice. An illuminating chapter on presently available strong alloys, including recently developed forms of high strength steel, is followed by a long chapter on the dynamics of fibre reinforced composites. A final chapter is concerned with the practical methods of making these.

The last two chapters include much very recent material, a good deal of it arising from the work of the author and his associates. They constitute the most readable and up to date survey of the reinforcement of plastics and metals by strong fibres. The early chapters deal with older subject matter, yet make stimulating reading, because the author has firmly resisted the temptation to spread his subject matter; he has not hesitated to use without proof formulae in the theory of elasticity or in dislocation geometry, for instance, but has incorporated them in the flow of his argument in such a way that its physical basis is always clear. Also he has been unusually careful to map out his plan of campaign at the start of each chapter, and at each stage to explain exactly what he is aiming at.

The book is up to the very high standards of the Clarendon Press. Apart from a slip near the foot of page 118 and a mysterious footnote on page 150, I found no errors. The book is recommended without hesitation to students of metallurgy, materials science and mechanical engineering, and to their teachers.

R. W. CAHN

### Nonlinear Electron-Wave Interaction Phenomena

By Joseph E. Rowe. (Electrical Science: a Series of Monographs and Texts.) Pp. xiv + 591. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 144s.

THE subject of this book is the non-linear analysis of the interaction between streams of charged particles and propagating electromagnetic waves. The theoretical foundations are laid with mathematical rigour in the first part of the book, while the remainder is devoted to the detailed application of the theories to various  $O$  and  $M$  type microwave tubes, and to some related techniques and problems. It is essentially a very full and systematic theoretical analysis of microwave tubes in which the theory has been developed with sufficient generality to be of

interest and use in other areas. One such area—beam plasma interactions—is dealt with in Chapter 12.

Particularly satisfying features of the book are its depth and the way in which problems are given alternative treatments together with critical discussions. These qualities are important in view of the fact that the book is written as a research monograph at a level appropriate to advanced graduate students. Knowledge of linear theory is assumed. The treatment is almost entirely theoretical, and one seldom finds experimental evidence in support of the theories developed. A consequence of dealing with non-linear equations is the difficulty of obtaining analytic solutions. There are therefore, as one would hope and expect, a large number of figures presenting computer results. The problem of gaining physical insight from such results is recognized, and is tackled with some success.

This book, which is well referenced and adequately indexed, is written with authority derived from wide research and teaching experience, and constitutes a valuable and readable contribution to the literature on microwave tubes.

I. B. BORT

### Thermal Neutron Scattering

Edited by P. A. Egelstaff. Pp. xv + 523. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1965.) 115s.

THE investigation of molecules, of liquids and of solids by thermal neutron scattering rests on the idea that the intensities of scattered particles which have lost energy and momentum are a measure of the density and corresponding spatial and time Fourier components of scattering power. The measurement of these intensities involves refined techniques of mechanical or diffractive velocity determination, and requires reactor sources, moderators, and scintillator detectors or proportional counters. This volume surveys the development of the subject since the great advances in technique during the fifties made it a productive field of study. Although there are fourteen different authors, the unity of presentation is unusually good and as a consequence the book serves as an introduction to the subject that will be of value to the non-specialist molecular or solid state physicist. For the specialist, the volume will also be valuable, as the field is not over-endowed with review literature.

J. B. HASTED

### Beginning Geology

By H. H. Read and Janet Watson. Pp. 246. (London: Macmillan and Co., Ltd., and George Allen and Unwin, Ltd.; New York: St. Martin's Press, 1966.) 30s. net.

ALTHOUGH the layman can probably appreciate geology more easily than almost any other science, geologists (with a few notable exceptions) are notoriously bad at transmitting the essence of their subject to the uninitiated. Read and Watson's writings admirably fill this gap in communication. Unfortunately, their book is aimed primarily at schoolchildren, so that the style is sometimes reminiscent of a patronizing matey teacher. Otherwise, I have nothing but praise for this book. The scope of the book is the field of geology; this is comprehensively covered, while the treatment, though simple, is deep, and fairly complex concepts (often not dealt with adequately in supposedly more advanced text-books) are presented. The choice of examples—so important in any phenomenological science—is judicious, as is the choice of diagrams and photographs, while the layout both pleases and aids assimilation of the contents. Illustrations are drawn to a large extent from the British Isles, but the book is not nearly as chauvinistic as many others in this respect. Even if it were not so reasonably priced, this book would still be a worthwhile buy for those who are "beginning geology".

A. M. MARSHALL

## OBITUARIES

### Sir Denis Browne

SIR DENIS BROWNE, who died on January 9, can be called the father of paediatric surgery.

In his native Australia he was educated at King's School, Paramatta, New South Wales, and at the University of Sydney, where he obtained his M.B. He served during the First World War with the Australian Army Medical Corps. Afterwards he came to England and obtained his F.R.C.S. Most of his working life was spent at the Hospital for Sick Children, Great Ormond Street, where he was houseman, registrar and consultant. During the Second World War he was the leader of a surgical team in a casualty clearing station in the basement of the hospital. Browne's surgical interests ranged from genito-urinary surgery to orthopaedics, for which he developed and modified instruments, appliances and operations. He developed many instruments, including a needleholder, dissectors, plastic shears and tonsil forceps, and appliances which reflect his interest in the treatment of congenital deformities. There are splints for the treatment of club foot and harnesses for the correction of spinal deformities and congenital dislocation of the hip. He led the treatment of this last condition by means of closed reduction and manipulation. He perfected the technique for the manipulative treatment of talipes equinus—a form of club foot—and repaired hare lip and cleft palate. In other fields of child surgery his inventions included a transthoracic approach and incision to correct congenital heart deformities, and an operation for undescended testicle.

Among the awards which Browne received for his services to paediatrics was the Dawson Williams Prize, and he was an honorary member of the French Society of Urology. His other activities included his four terms as president of the British Association of Paediatric Surgeons and membership of the B.B.C. General Advisory Council. He was also an expert shot; he preferred to ride in taxis, and would never own a car.

### Dr. William Meggers

WILLIAM FREDERICK MEGGERS died of a heart attack on November 19, 1966, aged 78. In 1958 he had retired as chief of the spectroscopy section of the U.S. National Bureau of Standards, which he joined in 1914 as a laboratory assistant, with a B.A. from Ripon College, an M.A. from Wisconsin and a Ph.D. from Johns Hopkins University, all in physics.

His early work, carried out with C. G. Peters, produced measurements of the refractive index of air which were used for more than 25 years. Later he worked on the determination of atomic energy levels for the analysis of spectra, which he did very well and in very great detail. Meggers also utilized the neutrons from atomic reactors to transmute gold to a single isotope of mercury, which he used to produce his mercury 198 lamp. This lamp gives off a green spectral line so pure that its wavelength can be determined to one part in one billion. The wavelength of this light has served as a working standard of measurement in spectroscopy and metrology throughout the world. Meggers was also among the first to observe atomic spectra in the infra-red region.

Meggers was active on a number of committees concerned with spectroscopy, and in 1949–51 he was president of the Optical Society of America, which gave him its two highest awards. He also received medals from the Franklin Institute of Pennsylvania, the Department of Commerce and the University of Liège. After his retirement, Meggers remained as a guest worker at the National Bureau of Standards, and continued to contribute to research in atomic spectroscopy.

# The Solar Wind outside the Plane of the Ecliptic

by

P. A. DENNISON

A. HEWISH

Mullard Radio Astronomy Observatory,  
Cavendish Laboratory,  
University of Cambridge

The scintillation of radio sources caused by the interplanetary medium offers a means of studying the motion of the solar wind well away from the plane of the ecliptic, where direct measurements have so far been confined. Observations from a triangular arrangement of radio receivers (on 81.5 Mc/s) suggest that the solar wind is faster over the solar poles than in the plane of the ecliptic.

DIRECT measurements of the solar wind carried out from space vehicles have, so far, been confined to regions close to the plane of the ecliptic at distances of the order of one astronomical unit from the Sun. Interplanetary scintillation<sup>1</sup> provides a new technique for studying the solar wind over a much wider range of heliocentric latitude and radial distance, and some preliminary measurements of the drift motion of scintillation diffraction patterns across the surface of the Earth using two spaced observing sites have already been reported<sup>2</sup>. In this note an account is given of more extensive observations made between February and July 1966, using three observing sites. Both the magnitude and direction of the solar wind have been measured and evidence has been found that the wind velocity from the polar regions of the solar

atmosphere is significantly greater than that in the plane of the ecliptic.

A triangular arrangement of observing sites was used as shown in Fig. 1. The antennas at each site were transit instruments with similar collecting areas of about 800 m<sup>2</sup> and operated at a frequency of 81.5 Mc/s. Identical receivers having a time constant of 0.2 sec were used and data from the outstations were returned to Cambridge using G.P.O. telephone lines. Before April 10, a three-track pen recorder was used and the records were analysed as described before<sup>2</sup>. After this date the output of each receiver, sampled at intervals of 0.12 sec, was digitized and punched on a single paper tape. For the latter period, which included more than half the observations, data reduction was carried out entirely automatic-

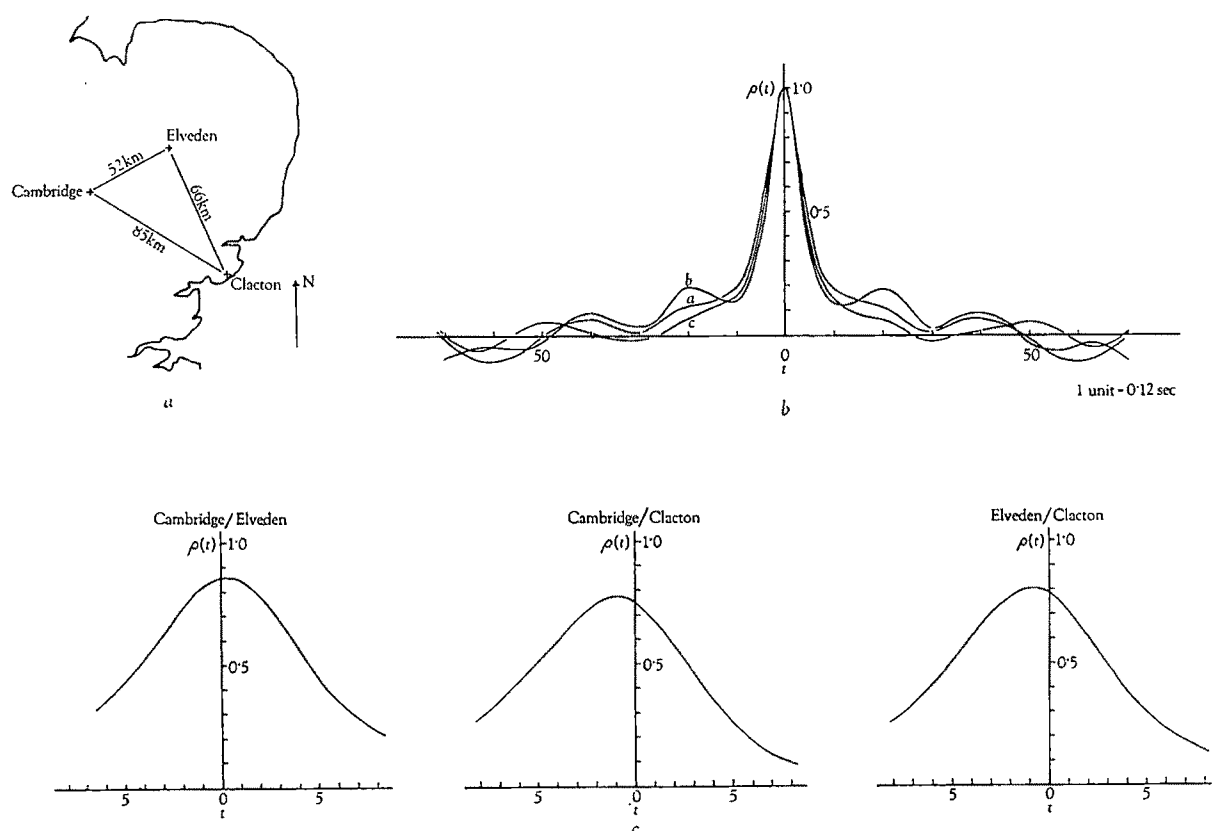

Fig. 1. (a) Location of the observing sites. (b) Typical auto-correlograms and (c) cross-correlograms derived from observations of May 9, 1966.

ally. Most of the measurements were confined to the radio source 3C 48; a few observations were also made using the small diameter component<sup>3</sup> of the Crab Nebula.

The analysis was confined to an interval of one or two minutes each day from which the auto-correlogram of each receiver output and the three cross-correlograms were derived. The results for a typical day are shown in Fig. 1. The fluctuations of intensity, the auto-correlogram of which usually decayed to  $e^{-1}$  in about 0.6 sec, were found to be highly correlated at the three sites, while the cross-correlograms exhibited systematic displacements of the order 0.1–0.2 sec.

The derivation of the drift velocity of a diffraction pattern using data of this kind is straightforward if the pattern is isotropic, while a slightly more complex analysis is necessary for the anisotropic case<sup>4</sup>. The present results were obtained by assuming that the pattern is isotropic; possible corrections arising from the errors in this assumption are believed to be small for reasons which will be discussed later. Noise fluctuations on the records led to a probable error of  $\pm 0.03$  sec in the time displacement derived from the observations on any one day, and this corresponds to an error of about  $\pm 10$  per cent in the derived velocity.

The magnitude and direction of the velocity of the diffraction pattern derived from the cross-correlogram data are shown in Fig. 2(a). It is seen that the direction of motion across the ground varied systematically from a position angle of about  $+50^\circ$  in February to about  $-100^\circ$  in June. The broken curve in Fig. 2(a) shows the expected direction calculated for an assumed radial outflow from the Sun, after making a small correction for aberration caused by the orbital velocity of the Earth, and it is seen to fit the observations within the experimental uncertainty of  $\pm 15^\circ$ .

The average magnitude of the velocity, which varied from about 300 km/sec when the line of sight passed the Sun at a distance of 0.8 A.U. to 490 km/sec at a distance of 0.36 A.U. where the line of sight crossed the polar region of the solar atmosphere, is shown in Fig. 2(b). In relating the velocity of the diffraction pattern to the solar wind the effect of integration along an extended line of sight must, however, be taken into account. The observed velocity represents a weighted average the value of which is dominated by the regions of greatest scattering which occur where the line of sight is closest to the Sun. On either side of this region apparent motion perpendicular to the line of sight corresponds to a resolved component of the

true radial velocity. Estimates based on the observed radial dependence of interplanetary scintillation<sup>1,5</sup> suggest that the true velocity may be 5–10 per cent greater than the values shown in Fig. 2(b). The random day to day changes of velocity are frequently greater than the experimental error and are believed to be real.

During the period of observation the heliocentric co-ordinates ( $p, \phi$ ) of the point of closest approach of the line of sight varied as shown in Fig. 3(a), and in Fig. 3(b) the observed velocities have been plotted as a function of these co-ordinates. There was a significant increase of velocity as 3C 48 approached the Sun, which might be associated either with decreasing radial distance or with increasing heliocentric latitude. The possibility that this increase was caused by temporal changes in the solar atmosphere, rather than by a systematic variation of heliocentric co-ordinates, does not seem likely, because the increase was maintained for a period of at least two weeks during which there was no outstanding solar activity.

Further measurements on other radio sources are needed to show that the increase of velocity is primarily a function of heliocentric latitude, although it seems unreasonable that the velocity should increase with decreasing radial distance since gravitational deceleration is negligible. Some limited data have been obtained from observations of the scintillating component of the Crab Nebula during July 1966, and the results are shown in Fig. 3(d). At this time the line of sight lay close to the plane of the ecliptic, but observations at distances less than 0.4 A.U. were unfortunately not possible because of the decrease of scintillation at small angular separation which has been noted before<sup>3</sup>. For  $p \approx 0.4$  A.U. an average velocity of 295 km/sec was obtained as compared with 420 km/sec derived from observation of 3C 48 at the same radial distance. This result strengthens our earlier supposition that the solar wind has a greater magnitude at high heliocentric latitude. Further evidence is provided by the rate of scintillation on other sources<sup>1</sup> which has been shown to increase with heliocentric latitude in a manner consistent with the same picture.

In addition to measurements of velocity it is also possible to draw conclusions about the scale and life-time of the diffraction pattern. Precise results require careful consideration of the effects of random noise in the separate records which become important when, as in the present case, the pattern is highly correlated at the three observing sites. Analysis of the cross-correlograms following the

Fig. 2. (a) Observed direction of motion of the diffraction pattern across the ground. The broken curve shows the direction expected for a strictly radial outflow from the Sun. (b) The magnitude of the drift velocity.

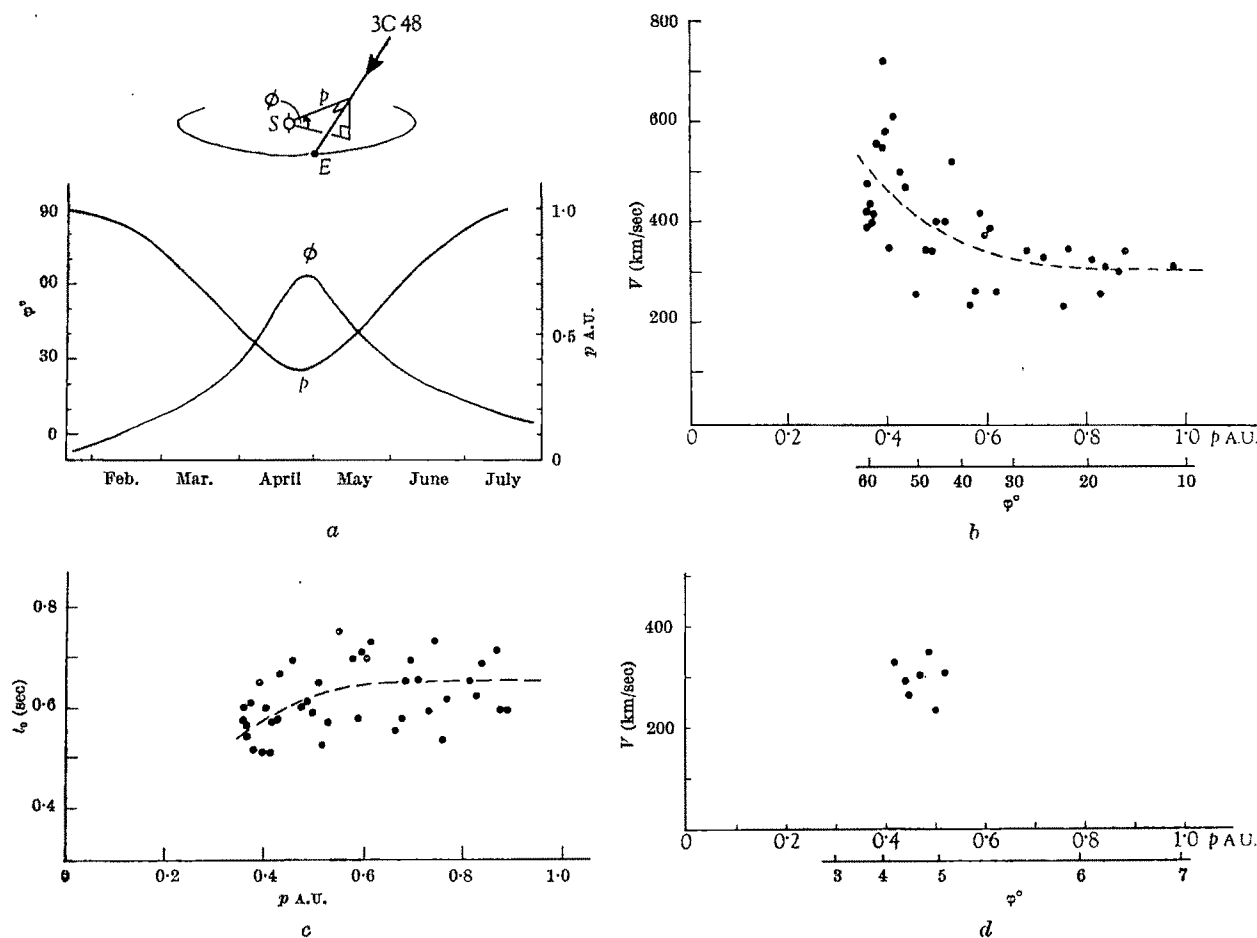

Fig. 3. (a) Heliocentric co-ordinates of the point closest to the Sun on the line of sight to 3C 48. (b) The observed velocity as a function of heliocentric co-ordinates for 3C 48. (c) Width (to  $e^{-1}$ ) of the auto-correlogram of the temporal fluctuations of intensity. (d) Observed velocity derived from observations of the Crab Nebula.

method described by Phillips and Spencer<sup>4</sup> indicates that the spatial correlation falls to  $e^{-1}$  in a distance of about 160 km. Since it has been shown that the interplanetary medium is a weak scatterer for  $p > 0.5$  A.U. (ref. 8), it follows that this remarkably small scale reflects the true size of the plasma density fluctuations themselves. The scale derived from cross-correlation does not differ significantly from estimates of the scale derived from auto-correlation on the assumption that the temporal fluctuations at one site are caused entirely by the drift motion of an unchanging pattern. It follows that the life-time of the pattern must be longer than the correlation time of 0.6 sec. The correlation time observed for various positions of 3C 48 relative to the Sun is shown in Fig. 3(c) where the heliocentric co-ordinates refer to the point on the line of sight closest to the Sun. It is seen that the correlation time decreased as 3C 48 approached the Sun, a result which is anticipated in view of the observed increase of velocity of the diffraction pattern. The decrease of correlation time is, however, not as large as would be expected and this leads to the conclusion that the scale of the diffraction pattern is somewhat greater when the line of sight is closer to the Sun. This effect is probably associated with the changing distance of the Earth from the dominant diffracting region and does not necessarily imply that the plasma irregularities themselves are larger when close to the Sun. For a line of sight such that  $p \approx 0.4$  A.U., the strongest irregularities are 0.9 A.U. distant from the Earth while for  $p \approx 0.9$  A.U. their distance is only 0.4 A.U. Now the diffraction pattern can only contain amplitude variations the lateral scale of which is smaller than the Fresnel zone radius, and it

follows that, if the irregularities in the medium have a range of sizes, then the scale of the pattern will tend to increase as the distance from the diffracting region is increased. This phenomenon could readily account for an increase of scale for small values of  $p$ .

The scale of the diffraction pattern derived from cross-correlation is slightly elongated in a direction parallel to its motion, but the mean axial ratio of the characteristic ellipse is less than 2:1. Such an elongation might be expected since earlier measurements of the angular spectrum of radio waves scattered by the interplanetary medium have given evidence for decreased scattering in a radial direction<sup>6,7</sup>. The possibility that the elongation of the pattern is caused by the shape of 3C 48 itself cannot, however, be eliminated. A detailed consideration of the effects of source diameter has been given elsewhere<sup>8</sup>, and it has been shown that a source extended preferentially in one direction can give rise to an elongated pattern. There is evidence that the angular dimensions of 3C 48 are critical in this respect, since this source scintillates somewhat less than other sources, and further information is needed before the elongation of the pattern can be ascribed to the interplanetary medium. Phillips and Spencer<sup>4</sup> have shown that the simple auto-correlogram analysis can give rise to errors of up to 20 per cent in the derived velocity when applied to a pattern which is elongated by a factor of 2:1. The errors fall to zero when the elongation is along the direction of motion, however, and it follows that the assumption, mentioned earlier, of an isotropic pattern for deriving velocities is justified.

Further attempts have been made to relate the occurrence of scintillation with solar activity. It is possible

Fig. 4. Day to day variation of scintillation index  $F$  and sunspot number.

that a small correlation with sunspot number exists, but the present data are barely significant. In Fig. 4 the scintillation index observed during 1965 and 1966 is shown together with sunspot number for the same period. The scintillation index on March 13 and 14, 1966, increased to about twice its average value and this may be connected with a limb-flare which appeared on the eastern edge of the disk at heliographic latitude  $20^\circ$  N. on March 14. Radial ejection of material from such a point would have passed close to the centre of the line of sight. Further events of this kind are needed, however, before a definite association may be regarded as established. While the scintillation index varies considerably from day to day, the observed velocities, particularly at low heliocentric

latitude, are remarkably constant. This result contrasts with space-probe measurements of the solar wind which have shown larger variations strongly correlated with  $K_p$ . It appears that variations of this kind must be averaged out by integration along a line of sight which implies that the differences of velocity are confined to relatively narrow streams in the interplanetary medium.

In an earlier paper<sup>6</sup> it was found necessary to assume a slight convergence of the solar wind towards the plane of the ecliptic. This suggestion was put forward to explain the slow radial variation of the measured width of the angular spectrum of radiation scattered by irregularities for  $p < 0.4$  A.U. The present measurements are not sufficiently accurate to detect the difference (about  $10^\circ$ ) from a strictly radial direction predicted by this model.

This work was financed by the Science Research Council, to whom one of us (P. A. D.) is indebted for a maintenance grant. We also wish to thank Viscount Elveden and Mr. Frank Hyde for their help in providing outstation facilities.

## How to count Quasars

by

PETER KAFKA

Max-Planck-Institut für Physik und Astrophysik,  
München, Germany

Bias in the counting of quasars can arise partly from the scatter of intrinsic brightness and partly because of the shapes of quasar spectra. The corresponding selection effects can be eliminated for any cosmological model assumed. This procedure will be important for the evaluation of future catalogues of radio sources. At present, no decision can be made, from a statistical count of quasars, between steady state and other cosmological models.

THERE is some disagreement in recent papers about the meaning of relations between the observed numbers, red-shifts and brightnesses of quasars. The main source of premature conclusions appears to be the fact that important selection effects have not been taken properly into account.

Veron<sup>1</sup> and others used the uncorrected plots of  $\log N/\log S$ ,  $\log z/\log S$ , or  $\log N/\log z$ . ( $N$  is the number of objects brighter than the flux density  $S$  at some observed frequency,  $z$  is the red-shift.) From the slope of about  $-2$  in the plot of  $\log N/\log S$  for the quasars in the revised 3C catalogue (3Crev), Veron concluded that there are relatively more quasars at larger distances and that one probably would have to explain that as an effect of the evolution of the universe.

Hoyle and Burbidge<sup>2</sup> expressed the opinion that the  $S/z$  relation of quasars is very hard to understand in a cosmological theory. This was contradicted by Roeder

and Mitchell<sup>3</sup>, who computed the intrinsic brightnesses (in special world models) and showed that their large scatter causes the apparent lack of correlation in the  $S/z$  plot. They did not, however, discuss the selection effects and their suggestions about "evolution effects" appear therefore to be premature.

I have found that the slope of about  $-2$  in Veron's plot of  $\log N/\log S$  is a consequence of selection effects and that after the elimination of these effects from samples now available no final conclusions can be drawn concerning the cosmological model and the space-time distribution of quasars. The method I use (which is programmed on a computer) may, however, be useful for the evaluation of future more complete observations. The details will be described in a more extensive report (Kafka, P., *Institutsbericht from the Max-Planck-Institut für Physik und Astrophysik*, in preparation).

Bright sources are seen up to large distances, weak ones only in our neighbourhood; moreover, distant ones are observed at a higher frequency of emission, where (in our case) their spectral intensity curves are lower. To eliminate the selection effects arising from these facts, we have to start with a statistical sample of objects for which all quantities that influence their visibility are known. The sample will be a catalogue of all sources brighter than some limit at some observed frequency. The 3Crev would supply a good statistical sample if all quasars in it were

identified. As this is not yet the case, an additional selection effect may come in that cannot be eliminated, because we do not know why one source is optically identified (and its red-shift measured) and another is not.

To demonstrate the method that should be applied when the red-shifts and radio spectra of all quasars in a complete catalogue (with a given flux limit) are measured, we shall eliminate at least the selection effects that will be important in this case. They can be treated now, although

Fig. 1. *a*, Intrinsic spectra for  $q_0 = -1$ ; *b*, intrinsic optical luminosity for  $q_0 = -1$ ; *c*, dependence of the intrinsic brightness (at 1,000 Mc/s) on the model. (Examples for various distances.)

Fig. 2. *a*, Steady-state model ( $q_0 = -1$ ); *b*, steady-state model ( $q_0 = 5$ ).

the present investigation is based on only thirty-one quasars in the 3Crev for which there is sufficient information.

In addition to the 3Crev flux data at 178 Mc/s the flux densities at 750 and 1,400 Mc/s, given in the NRAO catalogue<sup>2</sup>, are used. Thus for an object with red-shift  $z$  the intrinsic spectrum from  $178 \cdot (1+z)$  to  $1,400 \cdot (1+z)$  Mc/s can be computed.

To compute the intrinsic spectral intensities from the observed ones, one has to choose a cosmological model. I have used the Friedmann models without a cosmological constant, for different values of the deceleration-parameter  $q_0$  (which is proportional to the present matter-density), and the steady-state model. (The method can easily be extended to models that introduce unknown forces besides gravitation or the sourceless "force" of a cosmological constant.)

In Fig. 1a a common range of the intrinsic radio-spectra obtained is shown. As their slopes do not depend on the model, they are plotted only for one model. (Here the steady-state model is chosen, because it yields the widest spread of luminosities.) Fig. 1b shows the approximate intrinsic luminosity at  $1.4 \times 10^{15}$  c/s (2140 Å), obtained by interpolation (for mean red-shifts) or by extrapolation (for small and for large red-shifts) from the observed  $V$ ,  $B$  and  $U$  magnitudes. They are plotted for the same model. (From the correlations between intrinsic radio and optical luminosities one might try to find out in which direction a selection effect, arising from the identification problem, might influence results.)

In Fig. 1c the intrinsic luminosities of some quasars at 1,000 Mc/s for different values of  $q_0$  are plotted. The points for each object are connected by a line. The amount of power-output and even the order of brightnesses vary considerably with the model.

We are now ready to eliminate the selection effect which arises from the scatter of intrinsic brightnesses and from the shape of the spectra. From the intrinsic spectra we compute the distance at which each object would have to be in order to be seen (with a given model) at the flux limit of the catalogue, that is, 9 flux-units at 178 Mc/s. Then we compute the spherical space-volume,  $V_{\text{lim}}$  (at the present time), which corresponds to that distance. (The volume,  $V_{\text{lim}}$ , at the present time is proportional to the volume in co-expanding co-ordinates and therefore can be used to compare parts of the expanding homogeneous space.)

Only those objects which could be seen by us if they were anywhere in a chosen volume  $V_0$  (that is, objects for which  $V_{\text{lim}} \geq V_0$ ) are selected. Only those objects must be counted in the volume  $V_0$ . From that subset we plot the logarithm of the number of objects that lie in a volume  $V$  around us as a function of  $\log V$ , for  $V \leq V_0$ . Roughly speaking, choosing a larger  $V_0$  corresponds to counting only intrinsically brighter objects.

Repeating this procedure for increasing values of  $V_0$  a set of lines in the plane  $\log N/\log V$  can be constructed for each model. If these lines are used instead of the uncorrected plots of  $N/V$  the selection effects caused by the scatter of intrinsic brightnesses and the radio-spectra are eliminated.

The plots of  $\log N/\log V$  thus obtained, for different values of  $V_0$ , should be straight lines of slope +1 if the cosmological model chosen is a good approximation to reality and if we do not look too far back in time, where evolution effects may (and for Friedmann models finally must) come in. (Evolution effects in this sense might be a result of quasars originating at different rates or having different luminosities or spectra or life-times at different cosmical epochs. The objects themselves probably do not live very long.)

Figs. 2a and b show the plots of  $\log N/\log V$  constructed for the steady-state model and the Friedmann model with  $q_0 = 5$  (which are two extreme cases). The scale of volume is "cubic-Hubble", where the reciprocal Hubble constant, which may be about 4,000 Mpc (or  $13 \times 10^9$  yr),

is chosen as the length (and time) scale. Parallel to the  $V$  scale we show the red-shift  $z$ , the light-travel-time  $\tau$ , and the luminosity distance  $D$ . At the right-hand side of Fig. 2b the present horizon for this model is shown.

The circles represent the thirty-one quasars. A line through these points would be meaningless. (The crosses show the same plot for forty-nine quasars for which we have optical spectra and red-shifts, but for which we cannot eliminate the selection effect as the sample is not well defined.) The horizontal line beginning at each circle ends at the volume  $V_{\text{lim}}$  computed for the object. At the corresponding distance the object would be just seen with 9 flux-units at 178 Mc/s. Beyond that distance it would not appear in the catalogue.

The oblique zigzag lines connect the points at which the objects have to be counted after the elimination of the selection effects described. Each line corresponds to some value of  $V_0$ . These lines should be straight, with a slope of +1, at least in the region of lower  $z$  (that is, not too long ago), if we had enough objects and picked the right model.

With our small total number the slope is very much disturbed by random fluctuations in the distribution of quasars, and it would not make sense, with our present sample, to rule out one model or the other by statistics. Nevertheless, in the steepness of the lines beyond  $z = 0.5$  for models with high values of  $q_0$  one might see a hint of an evolution effect, if one of these relatively young models should be right.

Fig. 3. Density of number of objects with intrinsic brightness (at 1,000 Mc/s) in a chosen interval.

Now we can tentatively compute the luminosity-distribution of the quasars. We select the objects in some chosen interval of intrinsic luminosity at some fixed emitted frequency, count each of these objects once per its volume  $V_{\text{lim}}$  (which is about the same for all objects within the interval) and add the number-densities obtained. We do this for intervals of intrinsic luminosity at 1,000 Mc/s, increasing by factors of 2. The numbers per unit volume obtained are plotted over the intervals.

Fig. 3 shows this plot for our two extreme models. To construct it for the Friedmann model we assume that there

is no evolution effect. This assumption is not very reasonable as the far quasars in young models are already quite near to the horizon, but otherwise we could not simply take the space density of sources. In the steady-state model there is by definition no evolution effect possible.

The distributions obtained for the other models lie between those for the two extremes. Naturally these curves contain all the uncertainty from the random fluctuations that was expressed in the zigzag lines of Fig. 2.

Nevertheless the rise in the number density at low luminosities may be real and important: Then one might find in a catalogue with lower flux limit many intrinsically weak quasars, and a continuous transition to the radio-galaxies. This would be expected if the quasars were the outburst stages of radio-galaxies. The luminosity distribution might then be interpreted in terms of time evolution of objects that are not necessarily very different in their initial power output. In this case the steady-state model—as seen from Fig. 1—would require about twenty-five times more initial power than a model with  $q_0 = 5$ .

Our preliminary result is that with the small number of thirty-one quasars no Friedmann model with reasonable age (when we take into account an uncertainty factor of 2 in the Hubble constant) is ruled out. Also the steady-state model is not significantly ruled out by the quasar counts. The opposite opinion of Sciama and Rees<sup>5</sup> seems to arise from overestimating the statistical significance. In order to be able to rule out with some reliability a model by a  $\chi^2$ -test, examining whether objects of one kind are distributed in space at random (say with a Poisson distribution), we need about 20–30 objects on one

“countline” in our diagrams! The steady-state model would be ruled out if more observations were to show a significant deviation from a slope of +1 in Fig. 2a. For the Friedmann models the situation is more complicated. Here a deviation can mean either that the model is wrong or that an evolution effect is seen. Perhaps this effect will not be important at least for  $z \leq 0.5$  (which corresponds to an age of 0.33 of the cosmical age  $t_0$  for  $q_0 = 0$  and to 0.58  $t_0$  for  $q_0 = 5$ . For  $q_0 = 0$  there is  $t_0 = 1$  Hubble, for  $q_0 = 5$  we have  $t_0 = 0.35$  Hubble.) The right model could perhaps be determined by this method if many weak quasars were found such as would be expected in the transition region to the radio-galaxies. Moreover the distant radio-galaxies could also be treated by this method. In any case very good and rich samples will be needed because the models do not differ very strongly in the region below  $z = 0.5$ .

Probably the method will lead to more positive results when all the quasars in the 3Crev are identified. Then there should be about 100, and we could be sure that no additional selection effect comes in (except possibly some corrections for absorption). Then we may be able to restrict the possible world models and perhaps tell something about what the number-density and the spectra of quasars were in earlier stages of the universe, so that we could learn whether quasars are early or late stages of galaxies or whether they are quite different objects (like, for example, the “birth of matter from singularities”).

## Oxygen Spectra in Dayglow, Twilight, and during an Eclipse

by

J. F. NOXON

Blue Hill Observatory, Harvard University,  
Cambridge, Massachusetts

There is evidence for a morning-evening asymmetry for the  $1.27\mu$   $O_2$  band in twilight, and the evening decay appears slower at high latitude. No appreciable variation in the dayglow intensity has been observed with latitude; the decreased dayglow intensity during an eclipse seems consistent with the theory involving production of  $O_2(^1\Delta_g)$  by photodissociation of ozone.

SINCE the original observation from an aircraft of the  $(0,0) \ ^1\Delta_g - ^3\Sigma_g^-$  band of  $O_2$  in the dayglow and twilight<sup>1</sup>, a number of additional measurements have been made using the same instrument. These include measurements of the  $1.27\mu$  band in the dayglow, morning and evening twilight and during two eclipses. This communication summarizes these observations and compares our results with the balloon measurements reported by Evans *et al.* in the accompanying letter<sup>2</sup>.

Fig. 1 shows the results of several twilight observations at middle and high latitude in 1965. It also shows revised twilight intensities for February 1962; as originally presented by Noxon and Vallance Jones the intensities had not been properly corrected for the  $O_2$  absorption feature at  $1.27\mu$  in the sky background. The pair of solid lines are the balloon twilight measurements of Evans *et al.*; the remaining line is derived from one of the winter twilight observations of the  $(0,1)$  band at  $1.58\mu$  by Gattinger and Vallance Jones<sup>3</sup>. Observation of a discharge through  $O_2$  has allowed us to set a lower limit of 30 on the intensity ratio of  $(0,0)$  to  $(0,1)$ ; the theoretical

intensity ratio is 100/1. All the aircraft observations have been corrected for  $O_2$  absorption above the aircraft using transmission factors calculated by Gattinger and Vallance Jones<sup>3</sup>. Their calculations were based on an  $A$  coefficient for the band of  $1.5 \times 10^{-4} \text{ sec}^{-1}$  which now appears to be about half the correct value<sup>4</sup>; pending a recalculation we have retained their values for the transmission. We can estimate the error as the actual transmission for a given air mass will be about equal to what they calculate for twice that air mass. The 1965 aircraft intensities, measured in the zenith, will thus have to be raised by about a factor of 1.5. The 1962 twilight was observed at  $70^\circ$  zenith angle and the correction is more difficult to estimate; a small extrapolation suggests that here the intensities should be raised by a factor of 2.

Bearing these corrections in mind an examination of Fig. 1 suggests that our evening and morning twilight observations at  $62^\circ$  N. (obtained during a non-stop east-bound flight) are in fair agreement with the balloon observations<sup>2</sup> at  $52^\circ$  N.; not only are the intensities comparable but the dramatic asymmetry between evening

and morning is evident as well. The last two points on the evening of July 27, however, are, if anything, higher than the preceding point and the twilight decay might thus appear to have levelled off at about 1 megarayleigh. But it was just at this time that the aircraft started to pass beneath a bright visible aurora of at least IBC II; this is the only occasion when the airborne spectrometer has been directed at a bright aurora. The anomalous twilight decay could be accounted for by an auroral contribution to the  $1.27\mu$  band of some 500 kilorayleighs; the corresponding intensity of the 0,1 band at  $1.58\mu$  would only be 5–10 kilorayleighs. Although an emission peak of about 100 kilorayleighs has been observed at  $1.58\mu$  in a bright aurora this has been interpreted as being caused primarily by  $N_2^+$  emission<sup>6</sup>. Nevertheless, previous ground based observations at  $1.58\mu$  certainly do not rule out the possibility of  $1.27\mu$  emission in a bright aurora of the magnitude we require and we consider auroral contamination to be the most probable explanation for the abnormally large intensity in this late twilight.

The other evening twilights, February 1962 and July 21, 1965, appear similar to both our July 27 twilight and to the balloon twilight when the error in transmission coefficients is recalled. At the same time it seems clear that the 0,1 band observation implies that in 1961 the 0,0 band was not only brighter but also decayed more rapidly in evening twilight than was the case when it later became possible to observe the band directly.

All the direct measurements of the  $1.27\mu$  band appear to show a rather similar decay rate after sunset, when plotted against solar depression angle, although the decay rate of balloon measurements may be less rapid. An interesting consequence of this is that a great difference exists in the time constant for the decay at different latitudes. When the intensities are plotted against local time the decay is nearly exponential for solar elevation angles between  $0^\circ$  and  $-6^\circ$ ; the evening twilight decay at both  $52^\circ$  N. and  $62^\circ$  N. has a time constant of close to 60 min, almost exactly equal to the radiative lifetime of the  $^1\Delta$  state. At  $35^\circ$  N. the time constant is only 25 min while the 1962 observations at  $20^\circ$  N. suggest a time constant of about 15 min.

Fig. 1. The points and hatched area show twilight measurements of the  $1.27\mu$  band from aircraft observations; the pair of solid lines are the observations of Evans *et al.*<sup>3</sup>; the 0,1 band data are from Gattinger and Vallance Jones<sup>3</sup>. The aircraft observations have been corrected to zenith intensities using the transmission factors calculated by Gattinger<sup>3</sup>. Our dawn measurements at  $-2^\circ$  and  $-7^\circ$  are upper limits; otherwise the random error is estimated to be 10 per cent.  $\Delta$ , July 27, 1965,  $62^\circ$  N. p.m.;  $\blacksquare$ , July 23, 1965,  $62^\circ$  N. a.m.;  $\bullet$ , July 21, 1965,  $35^\circ$  N. p.m.; hatched area, Feb. 4, 1962,  $20^\circ$  N. p.m.

The simplest interpretation of this is that there is a near equilibrium between excitation and destruction of the  $^1\Delta$  state during the twilight decay, as this will make the twilight intensity dependent only on solar depression angle and not on the latter's rate of change. But this interpretation then makes it more difficult to explain the evening-morning asymmetry; a near equilibrium means a relatively short lifetime for the excited state through collisional quenching and one can no longer take advantage of the long natural radiative lifetime in order to extend the evening decay and retard the morning rise. This was also the problem encountered by Gattinger and Vallance Jones<sup>3</sup> when they attempted to fit their theory to the rapid decay of the 0,1 band observed in 1961; in effect a near equilibrium had to be maintained between excitation of  $^1\Delta$  by photodissociation of ozone and its destruction by collision if the predicted decay was not to be too slow. It does seem possible that, if the theory were applied only to the  $52^\circ$  N. and  $62^\circ$  N. twilights, in 1965–66, a considerable departure from equilibrium might be allowable as the observed decay is no faster than would be expected from radiation alone. Under these circumstances one might expect the theory to produce a noticeable morning-evening asymmetry. But the low latitude decay, being more rapid, would presumably not be consistent with a large departure from equilibrium. In this connexion it is clear that a study of the morning-evening asymmetry at low latitude would be of considerable interest; it is our intention to pursue this in the near future.

In summary, the aircraft and balloon twilight observations both confirm the morning-evening asymmetry observed in the winter<sup>3</sup> and show that it is also very pronounced in the summer. On the other hand, the evening twilight seems almost as strong in summer as in winter; this is a marked contrast to the large seasonal effect observed in 1961 (ref. 3). The aircraft measurements do not reveal any pronounced effect of latitude on the evening twilight, apart from the auroral effect at  $62^\circ$  N. There also seems to be little difference between the February 1962 twilight at  $20^\circ$  N. and the later ones at higher latitude.

A number of measurements of the dayglow have been made from the aircraft: April 1962 at  $45^\circ$  N., July 1963 at  $50^\circ$  N., May 1965 at  $0^\circ$  and  $20^\circ$  N., July 1965 at  $50^\circ$  and  $60^\circ$  N. In all cases the zenith intensity fell between 13 and 20 megarayleighs; with new transmission coefficients we estimate that the range will rise to 20–30 megarayleighs, in reasonable agreement with the 30 megarayleighs reported by Evans *et al.* from their balloon flights in October 1965 and February 1966. There is then no evidence for any large variation with latitude or year in the summer dayglow brightness, nor does there appear to be any seasonal effect, at least in 1965. On the other hand, the intensities<sup>3</sup> for the (0,1) band in early 1961 are so large and decay so rapidly in the evening twilight that the dayglow must have been well above 30 megarayleighs. Fig. 1 makes this clear, particularly if the (0,0) to (0,1) ratio is taken as 100.

There is a very marked difference in the behaviour of the (0,0) band at the eclipses of July 20, 1963, and May 30, 1965. The observations at the earlier eclipse have been reported by Noxon and Markham<sup>6</sup> and have been discussed theoretically<sup>3</sup>. It was necessary to observe at over  $70^\circ$  zenith angle so that the line of sight passed out of totality above 40 km; nevertheless the long duration of partial eclipse and the approach to near totality led to a theoretical prediction of a seven-fold reduction in brightness by the beginning of totality. The observations, however, indicated an intensity of about 12 megarayleighs at second contact with a drop of less than 30 per cent having occurred during the previous 4 min. The implication would thus be that the pre-eclipse dayglow was more than 80 megarayleighs (more than 150 if improved transmission coefficients are employed). Unfortunately we were not able to measure the pre- or post-eclipse dayglow;

even so the dayglow intensities observed at other times make it difficult to accept the required large value. The only other possibilities are that the theory is wrong or that we encountered auroral contamination at 56° N. Although aurora was not observed well above the horizon during totality its presence in the line of sight near the horizon cannot be ruled out.

The observing circumstances were much more favourable in 1965; the eclipse was observed near the equator and in the zenith where totality was complete to well above 100 km; in addition, the duration of totality was 6 min instead of 1 min. The aircraft was not at its maximum altitude of 13 km and so the brighter sky background limited measurement to pre-eclipse and near totality measurements. On this occasion the dayglow was 15 megarayleighs before and after the eclipse, 3.5 megarayleighs at the beginning of totality and less than 1.5 megarayleighs after 4 min of totality, if the old transmission coefficient is used. Although no detailed theoretical calculation has been completed yet for the geometry of this eclipse, one might expect the predicted drop to be similar to that for the previous eclipse; the observed drop of nearly a factor of 5 is thus not likely to be far from the predicted value. The decay during totality has an effective time constant of less than 8 min, noticeably smaller than that for the evening twilight decay observed at low latitude in 1962. This rapid decay is not surprising; not only is the residual illumination cut off entirely but one also expects the bulk of the emission to be lower in the atmosphere with more rapid collisional quenching than during twilight, because of the difference in solar elevation angle. Further discussion requires a detailed theory; it would also be desirable to have a complete set of observations covering the entire course of an eclipse.

The theory for the 1.27 $\mu$  band<sup>3</sup> leaves a number of observations unexplained; these include the morning-evening asymmetry and the seasonal effect so pronounced in 1961. It appears likely that a proper theory will also have to explain a reduction in magnitude of the seasonal effect after 1961 as well as what appears to be the comparative independence of latitude and season on the part of the dayglow. The theory of Gattinger and Vallance Jones<sup>3</sup> is restricted to a pure oxygen atmosphere and also ignores possible dynamic effects resulting from vertical and horizontal transport. At high latitude, for example, zonal winds in the mesosphere sometimes attain velocities comparable with the ground speed of the sunset line and so may either accelerate or retard the apparent change with time in the concentration of long-lived species at twilight. Perhaps even more important is the role of hydrogen compounds in the chemistry of the mesosphere; for example, the recent work of Hunt<sup>7</sup> and Hesstvedt<sup>8</sup>, which indicates that the introduction of water vapour into the model considerably alters the predicted ozone distribution and changes the time constants for variation in this and other mesospheric components. One may hope that a more comprehensive theory which includes such effects may be of benefit in accounting for the behaviour of the 1.27 $\mu$  band.

### Balloon-borne Observations of Brightness Variations in the (0,0) Band of the (<sup>1</sup> $\Delta_g$ -<sup>3</sup> $\Sigma_g^-$ ) System of Oxygen in the Day and Twilight Airglow

THE (0,1) band of the (<sup>1</sup> $\Delta_g$ -<sup>3</sup> $\Sigma_g^-$ ) system of oxygen was first observed from the ground in the twilight airglow in 1958 (ref. 1). This band, at 1.58 $\mu$ , was subsequently observed often in the evening twilight, but never in the morning twilight.

The (0,0) band at 1.27 $\mu$ , although theoretically about 100 times stronger than the (0,1) band, is difficult to detect from the ground during the day because of re-absorption by oxygen in the lower atmosphere. Since the value of the band extinction coefficient is approximately (1.1 km)<sup>-1</sup>, aircraft observations are also subject to considerable absorption as well as contamination by scattered sunlight. Balloons furnish an ideal observing platform for this emission, because at 30 km absorption is small and the background scattered continuum is reduced by almost an order of magnitude from its value at 13 km.

A successful observation of the (0,0) band of the (<sup>1</sup> $\Delta_g$ -<sup>3</sup> $\Sigma_g^-$ ) system of oxygen in the day airglow, taken with a grating spectrometer in a plane at a height of 13 km, was first reported in 1962 (ref. 2). In 1964, however, Gopshtein and Kushpil<sup>3</sup> reported the results of two balloon flights which had been made in 1956. A "recording spectrophotometer" (filter photometer) was flown on a balloon to a height of 30 km and observations were taken for a few degrees around 20° solar elevation on an enhanced glow in the 1.25 $\mu$  region. Although the authors did not identify the emission it was undoubtedly the (0,0) band at 1.27 $\mu$ .

Recently, in a series of balloon flights with an interference filter photometer, the 1.27 $\mu$  (0,0) band has been observed continuously over a complete day from before dawn until after sunset. The photometer, which utilizes narrow and wide band pass interference filters centered at 1.27 $\mu$ , has a field of view 10° in diameter and was used at a zenith distance of 50°. Absolute brightnesses were obtained by comparison with a standard low-brightness source taken in conjunction with a calculated synthetic spectrum for the (0,0) band. A preliminary analysis of the results has yielded the curves shown in Figs. 1 and 2. The absolute brightness scales, although at this time

Fig. 1. Morning and evening twilight brightness variations of the 1.27 $\mu$  band of O<sub>2</sub> obtained from balloon-borne measurements at 30 km. A, Morning twilight, April 8, 1965, 58.5° N. (launched from Churchill, Manitoba); B, morning twilight, October 10, 1965, 52° N. (launched from Saskatoon); C, evening twilight, February 24, 1966, 52° N. (launched from Saskatoon). The curves have been drawn through a large number of points; the vertical bars indicate the relative error which may be present in one section of the curve.

Fig. 2. The diurnal brightness variation of the  $1.27\mu$  band of  $O_2$ . A, April 6, 1965,  $58.5^\circ$  N.; B, October 10, 1965,  $52^\circ$  N.; C, February 24, 1966,  $52^\circ$  N.

approximate, are certainly correct to within a factor of two. These brightnesses have been reduced to zenith approximately by multiplying by the cosine of the zenith angle. An estimate of the relative error possible in each curve is indicated by the vertical error bars.

Curve A in Fig. 1, obtained from measurements at  $58.5^\circ$  N. (launched from Churchill, Manitoba) on April 6, 1965, is believed to be the first balloon observation of the morning twilight rise of the  $1.27\mu$  band. Curve B shows the results of the morning twilight observed on October 10, 1965, at  $52^\circ$  N., plotted on a logarithmic scale as a function of solar elevation angle. The first balloon observation of an evening twilight, measured on February 24, 1966, at  $52^\circ$  N. (launched from Saskatoon), is represented by curve C. The emission increases from a nightglow value of about 100 kilorayleighs to a dayglow value of about 30 megarayleighs at a solar elevation of  $20^\circ$ . The nightglow value compared favourably with a value of approximately 85 kilorayleighs measured from a balloon with a Michelson interferometer by Gush and Buijs<sup>4</sup>. In the morning twilight, the emission begins to increase above the nightglow value at approximately  $-7^\circ$  solar elevation and then rises sharply towards the daytime value. In the evening it falls off more slowly. This is consistent with the relatively long lifetime of the  $O_2$   $^1\Delta_g$  state, estimated to be about 60 min<sup>5</sup> in the absence of collisional deactivation. The evening-morning asymmetry explains why Vallance Jones and Gattinger<sup>6</sup> and Vallance Jones and Harrison<sup>1</sup> observed the evening twilight emission frequently, but could not detect the emission in the morning twilight.

The variation of intensity throughout the day is shown in Fig. 2; here the results from the three balloon flights have been plotted on a linear scale as a function of solar elevation angle. The noon intensity peak in the February flight is not so large as that in the October flight. In October the Sun reached a peak elevation of  $31.5^\circ$ , while in February the Sun rose to only  $27.5^\circ$ ; consequently there is a gap in curve C. A dashed line connects the two portions of the February curve which are to be displaced until they join. For the section of the curves which overlap, the two flights appear to agree well with each other. At noon, on each curve, there appears to be a sharp drop in intensity which results in an asymmetry of about 100 per cent between the forenoon and afternoon values out to approximately  $10^\circ$  solar elevation. The

range over which the drops occur, while small in solar depression angle, is relatively long in actual time as solar elevation angle changes very slowly around noon.

An analysis of the ascent data from the flight of February 24, which was launched at approximately 1130 c.s.t. and reached 100,000 ft. shortly before local noon, indicates that the major portion of the  $1.27\mu$  emission originates from regions above those reached by the balloon photometer. This supports the interpretation of Vallance Jones and Gattinger<sup>6,7</sup>, who attributed the emission of the ( $^1\Delta_g - ^3\Sigma_g^-$ ) bands to the production of excited oxygen molecules by photodissociation of ozone in the Hartley continuum; this mechanism predicts that the emitting regions will be above 30 km.

## Axial Period of Actin Filaments

Actin is the main constituent of one of the two types of fibres that together operate the sliding filament mechanism of muscular contraction. The form of the actin helix has been examined, first by electron microscopy and, second (page 356), by X-ray diffraction.

### Electron Microscope Studies

CONTRACTION in many muscles is due to an interaction of two kinds of filaments, one containing actin, the other myosin. The positions of actin molecules relative to myosin molecules in the intact system have not yet been defined, even in the case of resting muscle<sup>1</sup>. One of the remaining uncertainties is the form of the actin helix. The most

recently published conclusions<sup>2</sup> are summarized in Fig. 1: they were based on electron micrographs of negatively stained preparations and were also consistent with the X-ray diffraction data of Selby and Bear<sup>3</sup>. These diffraction results did not specify precisely the number of subunits (molecules) per turn of the helix, or the pitch. But Worthington<sup>4</sup> deduced from diffraction patterns that the helix had a pitch of 820 Å and 15 subunits per turn.

The electron micrographs, however, appeared to show that the structure repeated at intervals of about 700 Å, and that if one described the filament as consisting of two strands of subunits wound round each other (Fig. 1), then the number of subunits per turn of the helix in each strand was either thirteen or a non-integral number close to thirteen. These conclusions were based on measurements of the axial period (about 350 Å) and the spacing of the subunits in a large number of filaments, and on a few exceptionally favourable pictures in which it was possible to count the subunits along several turns of the helix.

New measurements of the axial period in electron micrographs of negatively stained preparations have revealed that the results depend on the method used for making the preparation. The previous results<sup>2</sup> have been confirmed, but other methods have been found to give other results.

Filaments from two sources were used in these new studies. Natural filaments were separated from the cross-striated adductor muscle of the scallop *Pecten maximus* (obtained from the Marine Biology Laboratory, Plymouth), and synthetic filaments were made from rabbit skeletal muscle. The method used for obtaining the natural filaments was as follows. A small piece of muscle (approximately a cube of sides 5 mm), cut out of a scallop that could vigorously open and close its shell, was placed in about 25 ml. of 100 mmolar potassium chloride, 6.6 mmolar phosphate buffer, pH 7.0, with 5 mmolar magnesium chloride and 5 mmolar ATP (pH finally adjusted to 7.0). After 30–60 min the muscle was cut into small pieces, transferred to 6 ml. of fresh solution in the flask of a homogenizer, and homogenized for 20 sec at approximately 17,000 r.p.m. A brief centrifugation (a few seconds at about 3,000g) removed large fragments, and the filament suspension was then diluted, using the same medium, and preparations made for the microscope within a period not exceeding 1 h. In all these operations up to the time of making the preparations, the material was kept at 0–4° C. (The reason for choosing this particular isolation medium will be discussed in a later paper.) Synthetic filaments (*F*-actin) were prepared from rabbit skeletal muscle by two different conventional methods (those of Straub and A. G. Szent-Györgyi)<sup>6</sup>. Sometimes the protein was not purified: on other occasions the first *F*-actin was spun down and depolymerized, and then repolymerized using either 0.1 molar potassium chloride or 0.6 mmolar magnesium chloride (ref. 6). None of these variations appeared to affect the results.

All the preparations for the microscope were made on carbon films supported on copper grids. The variations in technique were as follows:

(1) A drop of the filament suspension was placed on the film, left for a few seconds and then washed off with 5–10 drops of 1 per cent uranyl acetate in water (pH 4.4). The last drop of stain was removed with filter paper and the preparation allowed to dry.

(2) As (1) except that several drops of unbuffered 0.1 molar potassium chloride were applied before the stain.

(3) As (1) except that the stain used was 1 per cent phosphotungstic acid adjusted to pH 7.0 or pH 5.8 with potassium hydroxide.

(4) The drop of filament suspension was washed off with 5–10 drops of glutaraldehyde before applying uranyl acetate. 2.5 per cent glutaraldehyde buffered at pH 7.0 with 0.1 molar phosphate was used.

(5) As (4) except that the fixative used was 1 per cent osmium tetroxide buffered at pH 7.0 with 29 mmolar veronal acetate.

Electron micrographs were taken at a magnification of about 40,000 in a Philips 200 instrument (double condenser; accelerating voltage 80 kV; objective apertures 20μ or 30μ). The lenses were switched on at least 1 h before any pictures were taken. The preparations made by the various techniques that have been compared (thirty-two preparations in all) were examined in random order over a period of about 1 year. Magnification was assessed every 2 weeks or so by taking pictures of one particular area in a diffraction grating replica which was always kept in the same specimen holder; the variation found was never more than 2 per cent. Frequent comparisons were made between pictures of this area in the replica taken close to focus and others taken at the particular focal setting that had been used just previously for recording from an actin filament preparation in another specimen holder. These comparisons showed that this source of error in estimating the magnification was less than 2 per cent. Measurements of the axial period in the filaments were made on the original micrographs viewed in a dissecting microscope (magnification  $\times 7$ ). Here the possible error in measurement was not more than 2 per cent. Taking all these sources of error into account, the comparisons between periodicities in the various preparations are therefore judged to be accurate to within 5 per cent.

One other technical point must be mentioned. Each measurement of periodicity was made on between two and six periods, most frequently on three. Longer sequences were not measured because it was interesting to record variations in periodicity along a given filament. On the other hand, it was considered that measurements of single periods would not be sufficiently accurate, because the limits of the periods are not sharply defined, and because under the conditions used for measurement one period spanned only about ten divisions of the scale.

The results are presented as histograms (Figs. 2–8). Those labelled “uranyl” (Figs. 2 and 5) are from preparations made by methods 1 and 2; because the results for these two methods did not appear to differ they have been pooled. For the same reason the results obtained with phosphotungstate at the two pH values used (7.0 and 5.8) have also been pooled.

The wide range of measurements in any one type of preparation is notable. Similar ranges were found in single preparations, and sometimes in the same micrograph or even along a single filament. Synthetic filaments as well as natural ones show these phenomena, which are not therefore due to damage during isolation from the muscle.

Comparing unfixed preparations made with uranyl acetate and with potassium phosphotungstate, the periods measured in the latter are shorter (compare Fig. 2 with Fig. 3 and Fig. 5 with Fig. 6). Because of the large difference in pH between these staining solutions, some preparations were made using potassium phosphotungstate at pH 4.4 (the same pH as the uranyl acetate) and others using a solution containing uranyl acetate at pH 7.0 (ref. 7). The filaments in the latter preparations were so poorly contrasted by the stain that measurements could not be made. No filaments were found in the preparations made with phosphotungstate at pH 4.4. This last result suggests that uranyl acetate, which at the same pH does not dissolve the filaments, must act as a fixative.

Comparing preparations stained with uranyl and made with or without previous glutaraldehyde fixation, the measurements are similar in the two types of preparation (compare Fig. 2 with Fig. 4 and Fig. 5 with Fig. 7). On the other hand, filaments fixed with osmium tetroxide and stained with uranyl have shorter periods than those not treated with osmium tetroxide (compare

Fig. 1. Model illustrating the conclusions reached by Hanson and Lowy<sup>2</sup> about the form of the actin helix.

Figs. 5 and 8). (The histograms show this only for synthetic filaments; fewer measurements were made in the case of natural filaments, but those showed a similar trend.)

The previous measurements by Hanson and Lowy<sup>2</sup> were mostly made on filaments prepared with potassium phosphotungstate (pH 7.0 or 5.8) or fixed with osmium tetroxide. Their results (mean 349 Å, range 330–363 Å) were similar to those found here for such preparations. The new studies have shown that in other types of negatively stained preparations much higher values can be found for the axial periodicity. The shadowed preparations studied by Depue and Rice<sup>8</sup> gave much lower values, about 310 Å. The conclusion reached by Hanson and Lowy, namely that the actin polymer has thirteen or

nearly thirteen subunits per turn of the helix and an axial periodicity of about 350 Å (Fig. 1), is therefore not generally tenable.

In the studies reported here it was not possible to relate the number of subunits per turn of the helix to the axial periodicity. Counting of the subunits along one or more turns of the helix was usually impossible unless the filament lay across a stain filled hole in the supporting film where, however, distortion of the filament was liable to have occurred<sup>2</sup>. It is therefore not known if the wide range of values found for the periodicity in filaments lying on the supporting film is due to various degrees of shrinkage or if, as seems more likely, it is due to variation in the form of the helix. The spacing of the subunits could not be measured with sufficient accuracy to help distin-

guish between these two possibilities. If the variability in the axial period reflects a genuine variability in structure, present in the filaments before preparing them for examination in the microscope, this would be of considerable interest.

An axial periodicity of about 400 Å (ref. 9) is visible in the *I*-substance in sections of vertebrate skeletal muscle. (The term "*I*-substance" is used to describe the material that extends from the *Z*-line to the *H*-zone and comprises the actin filaments together with other components<sup>10</sup>.) It has been argued<sup>2,9,10</sup> that this periodicity is not due to repetition of the actin helices. One of the bases for this opinion was the finding<sup>2</sup> that the axial period in *F*-actin and in isolated natural actin filaments, negatively stained, measured about 350 Å. But the new studies reported here show that actin filaments do not necessarily have a periodicity that is different from the value found for the repeat in the *I*-substance. There are, however, several other reasons for thinking that the periodicity seen in the *I*-substance may not be due to actin alone. Tropomyosin, one of the proteins that is very probably present together with actin, can form fibrous aggregates which show a repeat of about 400 Å (ref. 11). Moreover, using a similar method to form aggregates of *F*-actin, it has been found that sectioned aggregates of unpurified actin are transversely striated (with a repeat value that depends on the method of fixation but can be about 400 Å), whereas aggregates of actin prepared by methods that eliminate tropomyosin and other impurities do not show this striation in sections—in spite of the fact that similar aggregates of purified actin, examined in negatively stained preparations, show good alignment of the actin helices (Hanson and Weindling, unpublished results).

In current studies actin filaments isolated from muscles in different states (relaxed by removal of calcium, contracting, or in rigor) are being compared with one another and with synthetic filaments to ascertain whether there are any differences in axial periodicity. If differences can be established, then the negative contrast method used might be considered relatively reliable, or at least very useful. Meanwhile, it has to be concluded that electron microscopy has not yet given reliable information about the form of the actin helix.

I thank Professor Sir John Randall for his encouragement of this work, and Mrs. Susan Weindling for technical assistance, particularly for preparing *F*-actin. This investigation was supported in part by a research grant from the Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service.

### X-ray Diffraction Studies

ACTIN filaments appear to be an essential part of the contractile apparatus in all types of muscle. Electron microscope investigations of negatively stained material isolated from a variety of muscles have suggested that these filaments (about 80 Å in diameter) consist of two

helically wound strands of globular units about 55 Å in diameter, each unit probably representing one monomer of actin<sup>1</sup>. This structural picture of actin filaments is in essential agreement with earlier X-ray diffraction studies on whole muscle by Selby and Bear<sup>2</sup>. Their analysis, however, could not specify the length of the long period (that is, the pitch) of each of the helically wound strands. On the assumption that there is an integral number of monomeric units in each turn of this helix, the long period could be either  $2 \times 350$  Å (thirteen units per turn) or  $2 \times 410$  Å (fifteen units per turn). But there is, in fact, no reason to assume that the number of monomeric units in each turn is integral; the pitch of the helix could also lie anywhere near or between  $2 \times 350$  and  $2 \times 410$  Å.

The distance between the crossover points of the two strands of the helix can be measured directly in the electron microscope. This was done by Hanson and Lowy<sup>1</sup> and also by Peterson<sup>3</sup>, who found values of 350 and 365 Å respectively. A similar measurement (366 Å) was obtained by Huxley<sup>4</sup> for the long axial period in actin filaments which had heavy meromyosin attached to them. These measurements favoured a helix pitch equal to or near to  $2 \times 350$  Å. More recent work, however (see preceding article), has shown that the distance between the crossover points as measured in the electron microscope depends on the method of preparation, is highly variable, and can be more than 400 Å.

It is possible to determine the pitch of the actin filament helix from X-ray diffraction patterns if the reflexion spacings can be measured with sufficient accuracy. Worthington<sup>5</sup> compared the "59" and "27" Å reflexions from actin in dried *Helix* pharynx retractor muscle and concluded that his measurements favoured  $2 \times 410$  Å. On the other hand, W. Brown, K. C. Holmes, H. E. Huxley and A. Klug (personal communication) have compared the "59" and "51" Å reflexions from living relaxed frog sartorius muscle and their results favour  $2 \times 350$  Å. G. F. Elliott and M. Spencer (personal communication), using the whole series of moderate angle actin reflexions from glycerol-extracted rabbit psoas muscle, were unable to decide on a fixed, integral, helix pitch. Their results from some muscles favoured  $2 \times 350$  Å, those from others favoured  $2 \times 410$  Å.

It appears, then, that neither from X-ray diffraction nor from electron microscopy has it so far been possible to obtain a consistent value for the pitch of the actin helix. We now have some low angle X-ray diffraction patterns from living relaxed toad sartorius muscle showing reflexions at angles below those corresponding to the "59" Å reflexions, which, because of their position and shape as compared with the myosin layer lines, appear to be actin layer lines. Although a complete series has not been seen on any one pattern, these reflexions were counted inwards and were found to be consistent with there being six layer lines inside the "59" Å reflexion. This suggests that the "59" Å reflexion may be indexed as the seventh order of a basic periodicity of about 410 Å, giving a helix pitch of about  $2 \times 410$  Å.

In X-ray diffraction patterns from these toad muscles, and also from the living relaxed anterior retractor muscle of *Mytilus edulis* (ABRM) taken with sufficient low angle resolution, a reflexion can be seen at about 400 Å which is of the same general shape as the "59" Å actin reflexion (Figs. 1 and 2) and which is also off the meridian. The relative positions of the maxima along the layer lines are not easy to determine with any accuracy, because the reflexions are very streaked along the layer lines. The "400" Å reflexion appears to lie on the same row line as the "59" Å reflexion (that is, the first row line ( $J_1$ )), although it is just possible that it could lie on the second row line ( $J_2$ ). The  $J_2$  position is required by the model put forward by Selby and Bear<sup>2</sup> (but see their pages 76 and 77). A similar reflexion at 388 Å has been observed in living relaxed frog sartorius muscle by Huxley, Holmes and Brown. This low angle reflexion may also correspond to

Fig. 1. X-ray diffraction pattern from living relaxed toad sartorius muscle ( $\times c. 8.5$ ). (The "59" Å and "400" Å actin reflexions are indicated by arrows.)

the 400 Å layer line seen by Selby and Bear<sup>2</sup> in molluscan adductor muscle and to the 400 Å layer line seen by Worthington<sup>6</sup> in insect flight muscle. Electron microscope evidence suggests that the actin filaments in all these muscles have the same structure<sup>1,4</sup>, whereas this is not true of the other major component of the contractile apparatus: myosin filaments in frog and toad differ from the thick filaments in insect muscles, and again from the paramyosin filaments in the molluscan muscles. We conclude that the "400" Å reflexion, because of its shape and position, is most probably associated with the actin filaments—and probably lies on the first order layer line.

Using a Franks type of low-angle X-ray camera and a  $40\mu$  focal spot (see ref. 8), measurements were made on X-ray diffraction patterns from ten living relaxed toad sartorius muscles (for examples, see Fig. 1). The ratio of the "400" and "59" Å spacings ranged from 6.71 to 7.00 with a mean of 6.86 (standard deviation of the mean—0.03). This ratio is less than the 7.00 which could be expected from indexing the "59" Å reflexion as the seventh order of a basic period of about 410 Å. In the ABRM, where the "400" Å spacing is more diffuse and

difficult to measure than in the toad muscle, the "400": "59" Å spacing ratio averaged 6.6, over six muscles.

These measurements suggest that the pitch of the actin filament helix in these two types of muscle does not have an integral number of units per turn, but that the structure approximates more closely to one with fifteen units per turn than to one with thirteen. But this may not apply to all types of muscle. In the living striated adductor muscle of the scallop (*Pecten maximus*) there is a normal "59" Å actin reflexion, but the corresponding first layer line is at about 463 Å, giving a ratio of 7.9 (B. M. Millman and G. F. Elliott, unpublished results).

Densitometer traces of our patterns from toad muscle show that the reflexions from the actin filaments are three to four times as broad in the axial direction as those from the myosin filaments (Fig. 2). In general, intrinsic line broadening has one of two causes<sup>9</sup>. Either it arises from the limited extent of the diffracting system; or it is due to some distortion in that system, and the simplest distortion is that in which the parameters vary from point to point within the diffracting specimen. The broadening (ratio) due to a diffracting system of length  $1.6\mu$  (the myosin filament length) is of the order of  $10^{-4}$  at a wavelength of 1.54 Å, and this agrees with the measured broadening (corrected for instrumental effects) of the myosin reflexions on our patterns. In toad muscle, the actin and myosin filaments have (to the approximation valid for this calculation) the same length, so that the diffraction in broadening cannot be due to a difference in filament length.

To explain their observations on the relative intensities of the equatorial reflexions from living frog sartorius muscle, Elliott, Lowy and Worthington<sup>10</sup> suggested that the part of the actin filaments outside the A-bands might be more disordered transversely than the part inside (a radial temperature factor). They noted that it was not necessary to postulate any disorder within the actin filaments, and predicted that the axial actin pattern would be much less affected by the amount of overlap between the actin and myosin filaments. This has now been shown to be the case: patterns from muscles stretched to zero overlap have shown no increase in the intrinsic broadening of the actin reflexions. Also in the ABRM, where the actin filaments are probably very long, the width of the actin reflexions is much the same as in the toad muscle. Therefore the extra broadening of the actin reflexions cannot be due to a limitation either in the length of the whole actin filaments or in the length of the filament overlap, though other factors may be limiting. The extra broadening might be ascribed to a variation in the long period of actin filaments. Broadening due to parameter variation generally increases with diffraction angle<sup>9</sup>. In this case, however, variations in the long period will not greatly affect the axial repeat of the units. This implies that Bessel functions of a given order will be broadened equally, and the broadening of Bessel functions one removed in order may be very similar.

A variation of the long period has in fact been observed in electron micrographs of negatively stained preparations of actin filaments (see preceding article). It is possible that contraction is associated with local changes in this long period, but if so the overall distribution of values for this period does not change on contraction, for we have observed no change in the spacing or broadening of the "400" Å reflexion in our X-ray diffraction patterns from contracting muscle<sup>11,12</sup>.

We thank Professor Sir John Randall for his constant encouragement and Dr. A. Elliott and Professor Jean Hanson for

Fig. 2. Microdensitometer tracings from X-ray diffraction pattern from living relaxed toad sartorius muscle. Portions from three similar tracings made in directions parallel to the meridian. *a*, Along row line corresponding to the "59" Å actin reflexion; *b*, along the meridian; and *c*, slightly further from the meridian than *a*. The breadth of the "400" Å reflexion can be compared with that of the "59" Å actin and "144" Å myosin reflexions. ( $\times c. 16$ .)

many useful discussions. We thank Miss M. Kinchin and Mr. Z. Gabor for technical and photographic assistance, respectively.

## Two Different Excitatory Transmitters acting on a Single Molluscan Neurone

by

H. M. GERSCHENFELD  
P. ASCHER  
L. TAUC

Laboratoire de Neurophysiologie cellulaire,  
Centre d'Etudes de Physiologie nerveuse,  
4, avenue Gordon-Bennett, Paris

It is known that at least two different mediators (acetylcholine and a non-cholinergic transmitter) are responsible for the excitatory transmission occurring between neurones in the ganglia of the mollusc *Aplysia*. It has now been shown, by the use of selectively blocking chemicals, that excitatory synapses using different mediators sometimes co-exist on the same neurone.

PREVIOUS investigations of molluscan nervous systems<sup>1,2</sup> have shown that in different cells excitatory postsynaptic potentials (EPSPs) can be produced by at least two synaptic transmitters: a cholinergic one, exciting the so-called *D*-neurones, and an unknown non-cholinergic one, responsible for the EPSPs appearing in the conventionally named *H*-neurones. It is possible that other transmitters exist in these same nervous systems<sup>3</sup>. In the present investigation a complication of this pattern of excitatory transmission was observed. In some neurones of the visceral ganglion of *Aplysia* it was found that EPSPs recorded from the same cell could be due to the action of two different chemical transmitters.

Ganglia were isolated from *Aplysia* in a special chamber and perfused with sea water. The neurones were generally impaled with two electrodes, one of which was used for recording and the other for hyperpolarizing the cell to a desired potential level. A full account of technical procedures can be found elsewhere<sup>4</sup>.

The neurones investigated were situated near the caudal pole of the dorsal face of the visceral ganglion. They all had the following properties in common: (a) Orthodromic stimulation of some afferent nerves evoked "inhibition of long duration"<sup>5,6</sup>—the long-lasting hyperpolarization which is the defining characteristic of the CILDA cells (see ref. 3). (b) The proper combination of two adequate inputs to these cells produced presynaptic inhibition—a property analysed by Tauc in the cells labelled *P1* (ref. 5). (c) Ionophoretic injections of both acetylcholine and 5-hydroxytryptamine depolarized these cells<sup>6</sup>. (d) All these cells received complex excitatory inputs.

Excitatory inputs occurred "spontaneously" in these cells, but many EPSPs could also be evoked experimentally by electrical stimulation of the nerves. In order to record and analyse these EPSPs without interference from spike activity, the cells were artificially hyperpolarized ( $-70$  to  $-80$  mV). The nerves were stimulated

at intervals far enough apart to avoid the development of habituation<sup>7</sup> and/or presynaptic inhibition<sup>8</sup>. The polarity of stimulation was regularly alternated in order to avoid polarization of the electrodes. Threshold stimulation of the right pleuro-visceral connective produced in all cells studied a unitary EPSP which was probably monosynaptic. Other excitatory components appeared at higher intensities of stimulation. Stimulation of other nerves, such as the branchial, siphonal, or genital nerves, always produced composite EPSPs. None of the spontaneous or evoked depolarizing potentials was reversed when the potential of the cell was returned to the normal level. Consequently, they all can be considered as truly excitatory.

These synaptic activities were investigated during perfusion of the ganglion with *d*-tubocurarine (dTC). Fig. 1 shows the effects of such a perfusion on the unitary EPSP evoked in the neurone by the stimulation of the right pleuro-visceral connective (Fig. 1A) and on the composite EPSP evoked in the same neurone by stimulation of the branchial nerve (Fig. 1B). It is clear that the dTC progressively blocks the unitary input from the right connective, but does not modify the composite EPSP evoked by stimulation of the branchial nerve even after prolonged perfusions (up to 40 min) of dTC.

The upper records of Fig. 2 also show, in another neurone, the blockage by dTC of the unitary EPSP evoked by stimulation of the right connective. In the lower records it can be seen that dTC affects only partially the "spontaneous" synaptic activity which results from interneuronal firing, even after a long-lasting application.

The selective action of curare can also be observed on the different components of a composite EPSP evoked from a single nerve trunk. Fig. 3 shows such a composite EPSP evoked by strong stimulation of the right connective; the first waves of this EPSP disappear under dTC, while the two late ones persist.

All the effects of dTC could be observed with low ( $10^{-6}$  g/ml.) as well as with high concentrations ( $10^{-3}$  g/ml. —Figs. 1, 2 and 3). This seems to exclude the possibility that the EPSPs resistant to dTC were merely less sensitive to dTC.

It has been shown in sympathetic ganglion cells that some EPSPs resistant to dTC are sensitive to atropine<sup>8</sup>. This suggested the possibility that the two types of excitatory synapses on the CILDA cells be cholinergic, with one involving atropine-sensitive (muscarinic) receptors, and the other involving dTC-sensitive (nicotinic) receptors. It was thus tested to see if atropine would selectively block the dTC-resistant EPSPs. This result, however, was not obtained. Atropine depressed all EPSPs, and in some cases it depressed the dTC-sensitive input more effectively. It should be noted that atropine, unlike dTC, caused an increase in the latency of the EPSPs. Such an effect on the presynaptic fibres could at

Fig. 1. Differential action of dTC on EPSPs of a CILDA cell. Stimulation of the right connective (A) and of the branchial nerve (B). The first upward deflexion (arrow) in series A to the unitary, monosynaptic EPSP, in series B to an antidromic axonal spike. (1) Control. (2) After perfusion for 1 min with dTC ( $10^{-3}$  g/ml.). (3) After perfusion for 3 min. Note the persistence of "spontaneous" EPSPs in 4. (4) After washing for 30 min with sea water. Differences in artefacts in series A were due to the use of alternated polarities of stimulation (see text).

Fig. 2. Action of dTC on evoked and spontaneous EPSPs. In each picture the activity recorded by a single micro-electrode has been registered at two sweep speeds. In the slower recording (lower line) one can observe the "spontaneous" synaptic activity and (arrow) an EPSP evoked by stimulation of the right connective. This monosynaptic EPSP is shown in more detail on the expanded sweep (upper line). (1) Control. (2) After perfusion for 1 min with dTC ( $10^{-3}$  g/ml.). (3) After perfusion for 5 min. (4) Recovery after washing for 20 min.

Fig. 3. Differential action of dTC on EPSPs evoked by stimulation of the same nerve trunk. Maximal stimulation of the right connective. The first upward deviation (arrow) corresponds to the unitary, monosynaptic EPSP. (1) Control. (2) After perfusion for 1 min with dTC ( $10^{-3}$  g/ml.). The unitary EPSP is depressed, but the long latency ones persist. (3) After perfusion for 6 min. (4) Recovery after washing for 30 min.

least partially explain its non-specific blocking effects. In addition, it has been observed that atropine has a non-competitive blocking effect on non-cholinergic, 5HT receptors of CILDA cells<sup>9</sup>. Thus, the effects of atropine do not support the hypothesis that the dTC-resistant EPSPs involve muscarinic receptors, but rather imply that these synapses are non-cholinergic and co-exist, on the same cell, with cholinergic synapses. Such a situation has been encountered in the study of Renshaw cells of the cat's spinal cord. These neurones seem to receive a cholinergic input from ventral root stimulation, and a non-cholinergic input from dorsal root stimulation<sup>9</sup>.

The possibility was considered that the EPSPs which were not blocked by curare might be a result of electrical transmission. To evaluate this possibility, we observed the effects of hyperpolarization of the cell on the unitary input from the right connective and on the composite EPSP evoked by stimulation of the branchial nerve. It was found that both the EPSPs sensitive to curare and the EPSPs resistant to curare increased with increasing hyperpolarization, even at polarization levels at which there is a decreased membrane resistance as a result of anomalous rectification<sup>10</sup>. Moreover, the regression lines relating the amplitude changes of both EPSPs to the level of hyperpolarization tended towards the same inversion potential. This suggests that the two types of synapses operate chemically, and may involve the same ionic mechanism.

From the data presented here it can be concluded that in a single CILDA neurone some of the EPSPs are caused by a cholinergic transmitter; others by a non-cholinergic transmitter. The depolarizing effects of 5-hydroxytryptamine on CILDA cells<sup>6</sup> suggest that this amine could be the non-cholinergic transmitter, but definitive evidence of its identification has not yet been obtained.

# Melanin, a Possible Pigment for the Photostable Electrical Responses of the Eye

by

THOMAS G. EBREY

Department of Physics, University of Chicago,  
Chicago, Illinois

RICHARD A. CONE

The Biological Laboratories, Harvard University,  
Cambridge, Massachusetts

Some kinds of biological tissues generate fast electrical responses to intense light and both stable and unstable responses have been detected. The unstable response is known to be associated with visual pigments. The possibility that melanin may be responsible for the photostable response is supported by a study of electrical photoresponses from various tissues.

WHEN a visual receptor in a vertebrate eye is stimulated by an intense flash of light, it generates a fast electrical response—the early receptor potential (early RP) (refs. 1 and 2). Recently it was suggested<sup>3</sup> that a flash of light might generate similar fast electrical responses in all biological tissues containing oriented pigment, and K. T. Brown has since reported such an electrical response in the pigment epithelium-choroid complex (PE-CC) of the eye<sup>4</sup>. Unlike the early RP, this PE-CC response is photostable, being highly resistant to light adaptation. The PE-CC consists of the cell layers immediately behind the retina which are densely pigmented with melanin, which is photostable and therefore the most likely photopigment for this new response, but Brown reported that a similar photostable response could apparently be observed in the eye of the albino rat which is free from melanin. Consequently, on combining this with other evidence, Brown suggested that the photopigment for the PE-CC response was probably related to the visual pigments rather than to melanin, and that this unidentified pigment might be contained in myeloid bodies, which are paracrystalline structures somewhat similar to outer segments of visual receptors<sup>5</sup>, and which are found in the cells of the PE-CC in both pigmented and albino eyes<sup>6</sup>. Because this new response in some ways resembles the early RP from the visual receptors, myeloid bodies seemed likely sources for it.

The purpose of this article is to report that we have found that the action spectrum of this PE-CC response is flat, just as would be expected from a pigment like melanin, and that we have confirmed our previous work in which we found that there was no large photostable response in the eye of the albino rat<sup>7,8</sup>. Thus we conclude, in contradiction to Brown, that the photopigment for the PE-CC response is not related to the visual pigments, and that the myeloid bodies do not generate this response, but instead, that it is generated or augmented by melanin. This new electrical response of the PE-CC therefore appears to be fundamentally different from the early RP, because the early RP depends on visual pigments<sup>2,9</sup>.

Most of the techniques and apparatus used for this investigation have already been described<sup>2,7,8</sup>. The stimulus flashes were produced by xenon flashtubes with input energies of either 60 J (Fig. 1) or 200 J (Figs. 2 and 3). The stimulus flashes were focused on the preparations by lenses of high numerical aperture; their energy and wavelength were controlled by appropriate filters. A second light beam from a tungsten lamp was used as a steady background light to bleach visual pigments. The rate of quanta for the steady background light is about 10,000 times smaller than for the stimulus. Heat filters were placed in the tungsten beam to facilitate rapid bleaching. For whole excised eye recordings, wick electrodes were placed in contact with the cornea and the back of the eye, and the entire retina and PE-CC were uniformly illuminated by both the stimulus flashes and the bleaching light. All electrical artefacts were eliminated by shielding, and the responses were recorded photographically from oscilloscopes.

Almost all the characteristics of the PE-CC response which we have observed confirm or are consistent with

those reported by Brown for the marine toad, *Bufo marinus*<sup>4</sup>. For example, we have observed this new response from the isolated PE-CC layers stripped from the back of the toad eye, and also from the isolated PE-CC layers of frog and cow eyes. We have also observed this response from whole excised eyes of rat, guinea-pig, and goldfish, and in every eye the time-course and amplitude of the PE-CC response are comparable with those reported by Brown for the toad eye. In addition, we have found that the PE-CC response is not only unaffected by a long series of intense flashes such as were used by Brown, but is also unaffected by extended exposures to intense steady light. Thus, the PE-CC response definitely appears to be photostable. Furthermore, we have found that the amplitude of the major peak of the PE-CC response is proportional to the energy of the stimulus flash, even for our maximum flash energy, which was about 0.1 J/cm<sup>2</sup>. There is, however, one crucial point on which our findings differ from those of Brown—a point that is important for Brown's interpretation of his results. As already mentioned, he reported finding a response in the whole eye of the albino rat that was not abolished by a series of fifteen intense stimulus flashes. Because the early RP is photolabile<sup>1,2</sup>, this finding led Brown to assume that this was a PE-CC response rather than an early RP. We have also observed such an apparently photostable response in the albino eye, even after hundreds of stimulus flashes. But from the beginning of our research we have assumed that this is an early RP because it has been established that intense light flashes photoregenerate the visual pigments on which the early RP depends<sup>10,11</sup>. Recently, Arden and Ikeda have shown that the early RP is photoregenerated by such intense flashes<sup>12</sup>. With this in mind, we have always used steady light sources when attempting fully to bleach the visual pigments, and with such light we have always been able to reduce the amplitude of the early RP in the eye of the albino rat to less than 1 per cent of its maximum (dark-adapted) amplitude. In discussing the photolability of the early RP, Brown states that a series of flashes "abolishes" the early RP<sup>1</sup>. We do not find this to be the case, and we have refrained from using the term "abolish", stating only that with continuous light the amplitude of the early RP can be reduced "below the noise level of the preparation"<sup>2</sup> because we find that even after extended exposures to light, especially in the living eye, the early RP slowly recovers in the dark, and at a rate that can be attributed to the regeneration of the visual pigments. This recovery, by the way, provides some measure of assurance that the preparation has not been significantly damaged by exposure to light.

Fig. 1 illustrates the effect of a series of intense flashes on early RP and then, for comparison, the effect of a steady light. The early RP responses shown in Fig. 1 were obtained from whole excised eyes of the albino rat, a different eye being used at each of three different temperatures. The three responses in the top line (a) are from eyes fully adapted to the dark. After recording these responses, the eyes were stimulated at 2 min intervals by the same intense flash and the response to the fifteenth flash is shown in the middle line (b). This procedure for

Fig. 1. Effects of light-adaptation on the fast electrical responses of whole excised eyes of the albino rat at three different temperatures. Amplifier bandpass; 1–10,000 c/s. White stimulus flash, 0.7 msec duration. Flash energy such that about 1 quantum was absorbed by each molecule of rhodopsin during a flash. In Figs. 1 and 2 responses of positive polarity at the cornea are displayed as upward deflexions.

light adapting the eye is the same as that used by Brown. It can be seen in Fig. 1 that after such a series of flashes, a sizable response remains, especially at the higher temperatures (note amplification scales). Evidently this is the response that Brown ascribes to the PE-CC chiefly on the basis that it is so resistant to light adaptation. If the eye is exposed to a continuous bright light, however, this response rapidly diminishes in amplitude, and in 5 min the response is as shown in the bottom line of the figure (c). Here the response amplitudes are no more than 1–10 per cent of their dark-adapted values. With continued exposure the amplitudes continue to diminish. Thus, in the albino rat, virtually the entire response recorded from the whole dark adapted eye is photolabile to continuous light. It was important to establish this in our previous work on the early RP because it was necessary to determine whether the early RP was significantly contaminated by photostable responses. Our results show that in the dark-adapted eye of the albino rat, the early RP is essentially uncontaminated.

In the eye of the toad, however, as Brown has clearly illustrated and as we have confirmed, the early RP is severely contaminated by the photostable response of the PE-CC. Because this is an important question for future research on the early RP, we have investigated the extent of contamination of the early RP by the PE-CC response in two other animals—the normal (pigmented) rat for comparison with the albino rat, and the frog. The response recorded from a dark-adapted eye before any visual pigment has been bleached should consist of both the early RP and the PE-CC response. The degree to which the early RP is contaminated by the PE-CC response in

such a dark-adapted eye can be ascertained by comparing this dark-adapted response with one obtained after fully bleaching the visual pigments to eliminate the early RP and thereby to reveal the photostable PE-CC response. Presumably, the same PE-CC response should be present in both cases. To make this comparison we show in Fig. 2 pairs of responses to stimulus flashes of three different colours obtained before and after bleaching the visual pigments. By using different colours the individual contributions of the early RP and the PE-CC response can be further isolated. In the left-hand column of Fig. 2 the stimulus flash contained only light from the far red end of the spectrum. The visual pigments absorbed so little of this light that no early RP could be detected. But the energy of this far red flash was fully effective in stimulating a PE-CC response because, as will be considered later, this response is almost equally sensitive to all wavelengths of light. Thus, in Fig. 2 the responses to the far red flash both before and after bleaching the visual pigments are probably isolated PE-CC responses. These responses are photostable, as can be seen by comparing the first and second traces in each pair. In addition, because the same far red flash was presented to each eye, the relative amplitudes of the photostable responses in the eyes of the frog, rat, and albino rat can easily be compared. It is clear that an appreciable photostable response occurs in both the frog and the rat, but in the albino rat a response is barely detectable, and it is always somewhat reduced by extended exposures to bright light. We have not previously observed this small response in the albino rat eye, and have only observed it now with extremely intense flashes from a 200 J flashtube. It has some characteristics of a PE-CC type response, but its amplitude is an order of magnitude smaller than the amplitude of the PE-CC type response we observe in the normal (pigmented) rat.

In contrast to the PE-CC type responses produced by the far red flash, in the middle column of Fig. 2 a green stimulus flash was used to produce the largest possible early RP with the least possible contamination by the PE-CC response. In the frog, the early RP is relatively small (see amplification scale) and even with this green flash the early RP is significantly contaminated by the PE-CC response. But in the eyes of both the normal and the albino rat, the early RP is much larger, and is essentially uncontaminated, even though in the normal rat there is an appreciable PE-CC response. In the right-hand column of Fig. 2 we used a white flash, with maximum energy, and here, too, the early RP is essentially uncontaminated in both types of rat. In the frog, however, this flash produced a PE-CC response so large that the early RP can only be detected as a slight change in the wave-

Fig. 2. Fast electrical responses of whole excised eyes before and after bleaching the visual pigments. The first response in each pair of responses was obtained from a fully dark-adapted eye. The second response was obtained with the same stimulus flash but after fully bleaching the visual pigments by exposing the eye for 30–60 min with an intense yellow-green light. This bleaching light was adequately heat-filtered to keep the temperature of the PE-CC from rising significantly. Stimulus flash wavelength bands: far red, 710–1,000 nm; green, 460–560 nm; white, 350–1,000 nm. Approximate flash energy at the retina in J/cm<sup>2</sup>: far red, 0.03; green, 0.008; white, 0.1. Flash duration shown by photodiode tracing. Amplifier bandpass: 10–10,000 c/s. Temperature: 18°C frog; 37°C rat.

form of the PE-CC response on bleaching the visual pigments. In summary, the responses in Fig. 2 show that (1) a PE-CC type response can be isolated in all three animals by using a far red flash, (2) the early RP of the frog eye is significantly contaminated for all three stimulus flashes, and (3) in both the normal and albino rat, the early RP is only contaminated when using far red flashes.

We have observed the action spectrum of the PE-CC response in several animals to help identify the corresponding photopigment. Most of these action spectra were obtained from whole eye preparations to eliminate any possible effects of tissue damage, and also to clarify further the respective contributions of the early RP and the PE-CC responses. Action spectra of whole eye responses both before and after bleaching the visual pigments are shown in Fig. 3 for the same three animals used in Fig. 2. In dark-adapted eyes, the early RP dominates the whole eye response over most of the spectrum and, as has already been reported<sup>7,8</sup>, the resulting action spectrum corresponds to the appropriate visual pigments. At the far red end of the spectrum, however, the whole-eye response changes shape (see Fig. 2) and its action spectrum levels out. This far red response is photostable. Thus, the action spectrum for this response remains unaltered when the eye is exposed to a steady light that fully bleaches the visual pigments. After bleaching, a similar response is observed throughout the spectrum, and the action spectrum for this response is nearly flat. This is the same type of action spectrum as we observe from the isolated PE-CC, and thus the whole-eye response that remains after fully bleaching the visual pigments appears to be an isolated PE-CC response.

The flat action spectra of the PE-CC responses strongly suggest that the photopigments for these responses are not related to the visual pigments, but on the contrary absorb all wavelengths of light equally well. Black pigments such as melanin fit this requirement, and there seems a good possibility that melanin is primarily responsible for generating at least part of the PE-CC response. It is important, however, to note that a small PE-CC type response does occur in the melanin-free albino eye, and that the action spectrum for this albino response is much the same as in the pigmented eye. Thus it also appears likely that melanin may simply augment a response that is already present in the albino eye. In

either case, this evidence begins to rule out myeloid bodies as the source of the photostable PE-CC response. If myeloid bodies generate this response, it should be much larger in the albino eye, where the myeloid bodies are not shielded from the light by melanin. Instead, however, in the albino eye the PE-CC response is at least an order of magnitude smaller, or is absent altogether. Significantly, fast electrical responses quite similar to the PE-CC type response have now been observed from skin, and the action spectra for the fast responses in skin are flat, which again suggests melanin for the photopigment<sup>13</sup>. Moreover, we have observed PE-CC type responses from the back surface of the iris excised from the cow eye, and this surface is densely pigmented with melanin. But in skin, just as in the PE-CC, responses can be recorded from albino skin which are similar to but smaller than those from the corresponding skin containing melanin. Taken together, this evidence suggests that intense light flashes produce a fast electrical response in a variety of biological tissues even in the absence of melanin, but that melanin either augments this response or independently generates a major portion of it.

When melanin is present, all these fast photostable responses from PE-CC, iris, and skin have about the same amplitude for a given energy flash, and they all appear to have flat action spectra extending far into the red end of the spectrum. Brown has pointed out that the PE-CC response is in many ways similar to the early RP, and it is interesting that all these responses bear this resemblance. Because it depends on the visual pigments, however, the early RP is photolabile. Furthermore, for a given flash energy the amplitude of the early RP can be hundreds to thousands of times larger than these fast responses. Moreover, unlike these responses, the amplitude of the early RP saturates at high flash energies<sup>2</sup>. The effects of osmotic pressure and temperature are also different for the PE-CC response and the early RP. (The PE-CC response is greatly affected by glycerol-Ringer solutions<sup>14</sup> but the early RP is not. The amplitude of the early RP is greatly affected by temperature (see, for instance, Fig. 1), but the amplitude of the main peak of the PE-CC response is independent of temperature at least down to temperatures at which the tissue freezes, where changes are seen which are probably due to the same mode of action as the osmotic changes<sup>14</sup>.) These marked differences between the early RP and the fast responses which appear to arise from melanin may simply depend on a different mechanism of generation, or on a difference in photopigments, or on a difference in the distribution or association of the photopigments within the cell. Whether there is a real difference between the two types of responses has yet to be established, but further research with one type of response is certain to offer some insights into the other response.

This work was supported in part by grants from the U.S. National Institutes of Health to Harvard University and the University of Chicago. We thank Prof. John R. Platt, Mental Health Research Institute, University of Michigan, and Prof. W. L. Pak, Purdue University, for their advice.

Fig. 3. Spectral sensitivity of fast electrical responses of whole excised eyes before and after bleaching the visual pigments. The sensitivity is the reciprocal of the flash energy required to produce a response of a given amplitude (usually 20  $\mu$ V). The amplitude was measured from the baseline to the point of maximum excursion regardless of the type or mixture of responses present. Well blocked interference filters were used to limit spectral bandwidths to about  $\pm 10$  nm for most points, but points at the end of each action spectrum and all the points for the albino eye after bleaching were obtained with wide-band filters (approximately  $\pm 50$  nm). Temperature: 12°C frog, 37°C rat. Flash duration: 120  $\mu$ sec.

# Mechanism of Action of Amino-thiol Radioprotectors

by

P. E. BROWN\*

Lawrence Radiation Laboratory,  
University of California,  
Berkeley, California

How do amino-thiols protect living cells from radiation? One possibility is that they bind to and stabilize those parts of the DNA helix which are not covered by histones. This reduces both primary and secondary damage, and the DNA replication rate is decreased so that repair processes can act before alterations are replicated.

AMONG the chemicals which are known to protect living organisms against ionizing radiation there is one group, the amino-thiols, which is particularly effective, but despite the numerous papers dealing with the mechanism of action which have appeared, there is still no single theory explaining the prophylactic action of these and other compounds<sup>1-3</sup>.

With few exceptions, the most effective amino-thiols are those whose structures are closely related to that of cysteamine,  $\text{HS-CH}_2\text{CH}_2\text{-NH}_2$  (refs. 4-6). The corresponding disulphides are usually equally active, as are compounds which are readily metabolized to this type of compound<sup>7</sup>. Some generalizations derived from consideration of the structures of these prophylactics are: the amino and thiol groups must not be separated by more than three carbon atoms<sup>8</sup>, a free -SH group is required since thioethers are inactive<sup>8</sup>, alkylation of the amino group reduces, but does not destroy, activity<sup>6,9,10</sup>. Superimposed on these requirements are the subtle effects common in pharmacology; thus, although cysteine is a protector, when the amino and thiol groups are interchanged the product, isocysteine, is not only a non-protector but actually sensitizes living organisms to the action of radiation<sup>11</sup>. At the present time three theories have been thought to offer reasonable explanations, but none is entirely satisfactory alone<sup>1,3</sup>.

The idea that the induction of hypoxia or anoxia was the basis of protection followed from the recognition of the "oxygen effect", that is that the presence of oxygen during irradiation increases damage, but without oxygen natural recovery cannot occur. Another mechanism which has had wide support is that thiols act by destroying the free radicals produced by irradiation<sup>12,13</sup>. The third hypothesis is that of "mixed disulphide formation" advanced by Eldjarn and Pihl<sup>14,15</sup>. These workers believe that the thiol groups of enzymes are the radio-sensitive sites and argue that protective agents form transient mixed disulphides with the enzyme thiol groups. When a mixed disulphide is attacked by a free radical, one of the sulphur atoms is reduced while the other is oxidized so that the damage is reduced by roughly one half.

There are important criticisms of all three theories<sup>1,3</sup>, a common weakness being that neither the structural requirements nor the existence of apparently similar compounds which sensitize organisms to radiation can be explained<sup>16</sup>. Evidently some general unifying principle is needed to rationalize the known facts and to indicate the extent to which any of the above mechanisms may be involved. This article suggests what this principle might be.

There is ample evidence to show that DNA is the site of the primary radiation damage in cells<sup>17,18</sup>. The nature of the damage appears to be single strand breakage followed by deletions and chemical alterations of the bases together with dissociation of histones, if present<sup>19-24</sup>. It has been postulated that the damage is made good by a

repair system<sup>25</sup> and evidence for a most efficient repair system in *M. radiodurans* has recently been obtained<sup>26</sup>. The existence of the repair system is the first requirement for the mechanism proposed in this article.

We can assume that, in order to survive, a dividing cell must successfully replicate a set of nearly normal DNA. We can also agree with Guild<sup>25</sup> that if the repair system has an efficiency of the order of 99 per cent, then small alterations in the speed of repair could alter the amount of residual damage by a factor of three or more. In cases where the repair system is less efficient, however, small changes in the repair rate alone have little effect and the relative rates of three processes, damage, repair and replication, become the governing factors. Crudely we may say that so long as the rate of repair is greater than the rates of replication and damage, the cell should survive. This criterion breaks down, of course, when the rate of replication is so low that essential enzymes which are themselves damaged by radiation are not replaced. The importance of relative rates is borne out by the dependence of the lethal radiation dose on the dose rate<sup>27</sup>. This argument requires that the rates of repair and replication are independent of one another, and there is some support for this in the literature<sup>28</sup>. Thus, control of the three rate processes is required, and we now consider how amino-thiol prophylactics might bring about this control in the cases of replication and damage; there is insufficient knowledge of the repair process for it to be considered at present.

We first note that survival will be favoured by decreasing both the rate of damage and the rate of replication. There is a simple mechanism which would enable both these requirements to be fulfilled—binding to DNA.

If a substance binds to DNA the usual result is that the DNA helix is made more stable. Since DNA replication requires single strand separation<sup>29,30</sup>, the replication rate would be reduced by this increased stability. The mere presence of the binding agent, apart from tending to prevent the original breakage, would also tend to ensure physically that a break in a single strand would not lead to unravelling and consequent secondary damage. There is support for this conclusion in the literature. Thus, histones inhibit DNA dependent RNA and DNA synthesis<sup>29-31</sup>, and deoxynucleoprotein is less sensitive to ionizing radiation than DNA alone when acting as a primer for RNA synthesis<sup>32</sup>.

A feature common to histones is the presence of a large number of amino groups. This, together with the fact that aliphatic diamines are known to bind strongly to DNA<sup>34</sup>, makes it clear that a molecule with two or more amino groups is likely to bind to and stabilize any part of a DNA helix not covered by histone. This conclusion has led to the discovery that the disulphide forms of the amino-thiol protectors also bind strongly to DNA<sup>35</sup>, which explains the need for both the amino and free thiol groups in these protectors. For binding of this type to be relevant to protection, it is necessary for the disulphide form of the prophylactic to be the active one, but on this point there is controversy in the literature<sup>37-40</sup>. The conflicting evidence would seem to reflect the ease of

\* Present address: Department of Organic Chemistry, University of Adelaide, Adelaide, South Australia.

reduction of the disulphide (the overall metabolic tendency) and oxidation of the thiol (the *in vitro* tendency).

Binding to DNA is insufficient in itself to afford protection, for the aliphatic diamines, structurally very similar to the protective disulphides, are inactive. Evidently a disulphide link is necessary, and the reason for this may be closely related to the ease of reduction of the disulphide link in living tissue<sup>41</sup>. Certainly cystamine and cadaverine have different effects on RNA polymerase in certain circumstances, for example<sup>42</sup>. Reduction of the -S-S- bond would immediately free the DNA so that replication and repair could take place. This role of the disulphide link is supported by the fact that di(ethylaminoethyl)-sulphide,  $\text{EtNH-CH}_2\text{CH}_2\text{-S-CH}_2\text{CH}_2\text{-NH}_2$ , is inactive, though it should bind as well as, and have half the scavenging capacity of, the active diethylcystamine,  $\text{EtNH-CH}_2\text{CH}_2\text{-S-S-CH}_2\text{CH}_2\text{NH}_2$ <sup>6,11</sup>. With this mechanism in mind, we may proceed to consider the extent to which this hypothesis explains the more obvious aspects of prophylactic activity.

One of the most important structural requirements is that the amino and thiol groups should not be separated by more than three carbon atoms<sup>4-6</sup>. The present hypothesis explains this by referring to the work of Mahler and Mehrotra<sup>34,35</sup> on the effect of a series of normal aliphatic diamines on the melting temperature (stability) of DNA. These workers found that DNA was stabilized only if the number of carbon atoms between the two terminal amino groups was between two and ten. Stabilization of the helix was greatest with diaminopentane, and with diaminodecane had fallen to a very low level. Thus, when ten atoms are present in the chain between two amino groups we may expect very little effect; ten intervening atoms is just the number present in the first non-active aminothiols in its disulphide form, that is  $\text{H}_2\text{N-(CH}_2\text{)}_{10}\text{-S-S-(CH}_2\text{)}_{10}\text{-NH}_2$ .

The work of Mahler and Mehrotra revealed that certain diamines are capable of binding to DNA with a resultant decrease in the stability of the helix. The existence of binding agents which destabilize the helix provides an explanation of the existence of sensitizing agents<sup>16</sup>. Destabilization would lead to an increased rate of replication<sup>43</sup> so that more mistakes arising from primary lesions would be incorporated. Sensitization by compounds with structures very similar to those of protectors has not been adequately explained previously.

Whether a given diamine binds with stabilization or destabilization is dependent on its detailed structure; we can say that the most important factors governing this are the entropy effects associated with the interaction of the surrounding water with hydrophilic and hydrophobic centres in the bound molecule. Since these effects also govern water solubility, it is not surprising that in a closely related series of protectors such as the L-cysteine ester hydrochlorides there is a good correlation between protective capacity and water solubility<sup>2</sup>.

In view of the discovery that histones do, in fact, contain thiol groups<sup>44</sup>, it is tempting to modify the hypothesis slightly in order to include Eldjarn and Pihl's theory of mixed disulphide formation. The same result would obtain if the disulphide were formed between the protector and a thiol group of the nucleohistone; a portion of the DNA normally devoid of histone, and therefore a likely position for the development of damage after a primary lesion, would be stabilized by an easily removable binding agent. The attachment of the histone itself to the DNA would also be strengthened. This possible role of the histones might also provide a rationale for the difference between protection in mammals and in bacteria, for the latter are not known to possess histones.

All three of the earlier theories thus remain admissible as contributing mechanisms, though the present hypothesis suggests that a more fundamental mechanism is also required. The proposed hypothesis is summarized as follows:

Radioprotective aminothiols may act by binding to and stabilizing those parts of the DNA helix not covered by histones. This has two effects. First, apart from helping to prevent the primary lesion, the loose ends resulting from single strand rupture are held in place so that secondary damage arising from shortening or chemical alteration is prevented. Second, the DNA replication rate is decreased so that a repair process can deal with alterations before they are replicated. Binding of this type requires that the disulphide form of the protector is the active one and that the disulphide is necessary for ease of removal, so that repair and DNA and RNA synthesis may proceed. This enables certain structural requirements in the aminothiol protectors, and also the existence of radiosensitizers, to be explained.

The mechanism put forward in the above discussion thus appears to rationalize many features of radioprotection while fitting in with the current view on DNA structure and function. It is hoped that, in spite of the difficulties which will doubtless be found, the general scheme will prove to be valid and result in further understanding in this field.

I should like to thank Prof. Melvin Calvin for useful discussions, the U.S. Atomic Energy Commission for financial support, and the Science Research Council, London, for an abeyant NATO fellowship.

# Viral Specific RNAs in Infected Cells

by  
J. A. SONNABEND  
E. M. MARTIN  
E. MÉCS\*

National Institute for Medical Research,  
Mill Hill, London, N.W.7

Infection by RNA viruses is followed by the appearance of viral RNA in cells. As well as single and double stranded forms of the viral RNA another viral specific RNA can be found in chicken embryo fibroblast cells infected with the arbovirus Semliki forest virus. This may be concerned in the production of protein specific to this virus.

In cells infected with a variety of RNA viruses, there can be identified viral specific RNA distinct from that incorporated into virus particles (see Levintow<sup>1</sup>). Most often double stranded forms of the viral RNA have been described, but there have also been found in several instances species of viral RNA distinct from both the RNA of the infecting virus and from the double stranded form of viral RNA<sup>2-6</sup>. One of these additional species of RNA is sensitive, or only partially resistant, to ribonuclease; it is of low infectivity, and under appropriate conditions sediments in sucrose gradients between double stranded RNA and the RNA of the infecting virus<sup>2-4</sup>. It has been termed "interjacent RNA" by Martin<sup>6</sup>. There is evidence that the double stranded RNA is an intermediate in the replication of single stranded viral RNA. The role of interjacent RNA in virus growth is not known.

This communication describes the appearance of three distinct species of RNA in chick embryo fibroblasts (CEF) infected with Semliki forest virus (SFV)—an arbovirus containing RNA. A previous communication described a species of RNA in CEF infected with SFV, sedimenting more slowly in sucrose gradients than the RNA contained in the virus particle<sup>7</sup>, and it was thought that this component represented the double stranded form of SFV RNA because it was partially resistant to ribonuclease. Subsequent investigations have shown, however, that this component can be resolved into two distinct RNA species, one of which is highly resistant to ribonuclease. Resolution of the earlier described peak was made possible by comparing its sedimentation in sucrose gradients with that of the reaction product of an RNA polymerase isolated from CEF infected with SFV (ref. 8). This enzyme catalyses the incorporation of ribonucleoside triphosphates into RNA with characteristics of a double stranded molecule, and the reaction product of this enzyme has been shown to be identical with the RNA resistant to ribonuclease isolated from CEF infected with SFV (ref. 8).

The conditions for culturing CEF have already been described<sup>7</sup>. Cells were infected with a cloned stock of SFV at a multiplicity of 20–40 p.f.u./cell in the presence of 2 µg/ml. of actinomycin D by procedures previously described<sup>7</sup>. Under the conditions used, virus production commences at about 4 h after infection and maximum yields of viruses are obtained about 8 h after infection. The maximum rate of synthesis of RNA resistant to actinomycin occurs at 5.5 h after infection, but at 3 h after infection an early peak reaching 40–50 per cent of the maximum value is also seen<sup>9</sup>. RNA was extracted with phenol-sodium dodecyl sulphate from cells which had been exposed to tritiated adenosine or carbon-14 labelled uridine for various periods after infection. Linear sucrose gradients (5–20 per cent sucrose, 0.1 molar potassium chloride, 0.01 molar *tris* hydrochloric acid, pH 7.2, 0.001 molar ethylenediamine tetraacetic acid) were run in the SW 39 rotor of the Spinco model L ultracentrifuge

for 2.5 h. The methods used in the collection of fractions from the gradient, the preparation for counting tritium or carbon-14, and the examination of the infectivity, ribonuclease resistance, and radioactivity of the RNA have been described elsewhere<sup>7,9</sup>. Purification of SFV labelled with phosphorus-32 was by a modification of the method of Cheng<sup>10</sup>. Preparation of the SFV RNA polymerase, assays of the enzyme using tritiated guanosine triphosphate (<sup>3</sup>H-GTP) as the labelled substrate, and extraction of the reaction product have also been described elsewhere<sup>8</sup>.

Fig. 1 shows the distribution in a sucrose gradient of RNA extracted from SFV infected cells incubated with carbon-14 labelled uridine for 7 h after infection. Two main peaks of radioactivity are seen. One sediments at about 45 S and is infectious and sensitive to ribonuclease. The more slowly sedimenting component has a sedimentation constant of about 26 S and, after treatment with ribonuclease, a ribonuclease resistant component sedimenting at about 20 S is revealed. The infectivity in the 26 S–20 S region of the gradient is no more than 3 per cent of that in the 45 S region. The identity of the 45 S RNA with RNA extracted from purified SFV is shown in Fig. 2 where purified viral RNA labelled with phosphorus-32 was mixed with RNA extracted from infected cells labelled with tritiated adenosine, and run together in a sucrose gradient. It can be seen that the phosphorus-32 and tritium labelled RNA sediment in an identical position. RNA extracted from purified virus and 45 S RNA

Fig. 1. Sucrose gradient analysis of RNA extracted from CEF infected with SFV. Chick cells treated with actinomycin (2 µg/ml.) were infected with SFV (40 p.f.u./cell) and <sup>14</sup>C-uridine was added. RNA was extracted 7 h after infection, 0.25 mg chick ribosomal RNA was added, and the extract sedimented through a 5 to 20 per cent sucrose gradient. Fractions were assayed for infectivity (Δ—Δ), acid-insoluble radioactivity (●—●), acid-insoluble radioactivity resistant to digestion with ribonuclease (○—○), and optical density at 260 mμ (—).

\* Visiting worker from the Institute of Microbiology, Szeged, Hungary, in receipt of a research fellowship from the Wellcome Trust.

had a similar degree of sensitivity to ribonuclease when tested together.

Fig. 3a shows the sedimentation profile of  $^{14}\text{C}$ -uridine labelled RNA extracted from infected cells mixed before centrifugation with a reaction product of the RNA polymerase (labelled with  $^3\text{H}$ -GTP) isolated from CEF infected with SFV. Evidence that this enzyme is a viral specific RNA polymerase and that its product is a double stranded form of SFV RNA is presented elsewhere<sup>8</sup>. The enzyme reaction product sediments in an identical position to the ribonuclease resistant 20 S RNA present in infected cells. In the gradient shown in Fig. 3a, fractions

Fig. 2. Sucrose gradient analysis of RNA extracted from infected cells and purified Semliki forest virus. RNA was extracted from cells which had been treated with actinomycin, infected with SFV and then incubated with  $^3\text{H}$ -adenosine from 4 to 6 h. It was mixed with  $^{32}\text{P}$ -labelled RNA extracted from purified SFV and sedimented through a 5 to 20 per cent sucrose gradient. ●—●, acid-insoluble tritium radioactivity; ○—○, acid-insoluble phosphorus-32 radioactivity.

Fig. 3. Characterization of ribonuclease-resistant viral RNA. a, RNA was extracted from cells which had been treated with actinomycin, infected with SFV and incubated with  $^{14}\text{C}$ -uridine from 0 to 6 h. It was mixed with chick ribosomal RNA (0.25 mg) and with RNA extracted from SFV RNA polymerase after incubation in an enzyme assay system with  $^3\text{H}$ -GTP, and sedimented through a 5 to 20 per cent sucrose gradient. Fractions were assayed for acid-precipitable carbon-14 (●—●) and tritium radioactivity (○—○) and for acid-precipitable carbon-14 radioactivity resistant to digestion with 2  $\mu\text{g}/\text{ml}$ . of ribonuclease (●—●). b, As for a, except that the extracts were treated with 2  $\mu\text{g}/\text{ml}$ . of ribonuclease before gradient analysis. c, Fractions from the 20 S region of the gradient shown in Fig. 3a were pooled and diluted with 0.15 molar sodium chloride, 0.015 molar sodium citrate. Portions were heated at various temperatures for 8 min, rapidly cooled to  $-70^\circ\text{C}$ , and then thawed. They were incubated with 5  $\mu\text{g}/\text{ml}$ . of ribonuclease at  $25^\circ\text{C}$  for 30 min and acid-insoluble radioactivity was measured. Results are expressed as a percentage of the radioactivity in the unheated material before digestion with ribonuclease. The 30 per cent loss in radioactivity after treatment of the unheated sample with ribonuclease (dotted line) represents contamination with ribonuclease sensitive RNA.

Fig. 4. Synthesis of various RNA species during virus growth. Cells were treated with actinomycin, infected with SFV and incubated with  $^{14}\text{C}$ -uridine from the beginning of infection. RNA was extracted at various times for gradient analysis and determination of specific activity and specific infectivity. The proportions of the various RNA species were calculated from the sucrose gradient and the specific activity of each RNA component determined. The specific activities are expressed as a percentage of the specific activity of the 45 S RNA at 7.5 h after infection. ●—●, 45 S RNA; ○—○, 26 S RNA; △—△, 20 S RNA; x—x, infectious RNA.

were treated with ribonuclease after centrifugation. When the mixed RNA sample was treated with ribonuclease before centrifugation, there was a single peak of carbon-14 and of tritium in an identical position at about 20 S (Fig. 3b). Further evidence for the double stranded nature of 20 S RNA appearing in infected cells comes from studies on its melting temperature. The sensitivity to ribonuclease of RNA isolated from the 20 S region of a sucrose gradient after heating to various temperatures in 0.15 molar sodium chloride is shown in Fig. 3c. A sharp increase in ribonuclease sensitivity after heating to  $103^\circ\text{C}$  can be seen in Fig. 3c. Under the same conditions the reaction product of the SFV RNA polymerase has an identical melting temperature<sup>8</sup>.

The amount of each of the viral specific RNA components present during virus growth was studied by labelling cells with  $^{14}\text{C}$ -uridine at the beginning of infection and extracting the RNA at various times for infectivity determinations, measurement of its specific activity, and sucrose gradient analysis. The relative amount of each of the three RNA components at each time was determined from their distribution in sucrose gradients. From the specific activity of the total RNA a measure could be made of the amount of each of the species of RNA as infection proceeded. Fig. 4 shows the results of such an experiment. Infectious RNA and 45 S RNA increase in parallel, suggesting that most of the infectivity resides in this component (see also Fig. 1). Concentrations of 20 S RNA reach a maximum while 26 S and 45 S RNA are still increasing, and early in infection 26 S RNA shows the highest rate of synthesis. Only in the later stages of infection does 45 S RNA become a major component.

Of the three species of SFV RNA which appear in CEF, 45 S RNA is thus identified as the RNA incorporated into virus particles, and 20 S RNA is a double stranded form of viral RNA. The significance of the 26 S RNA component is unknown. It is unlikely that it represents 45 S RNA associated with ribosomal RNA. The infectivity of 26 S RNA is low or not detectable, and in uninfected cells in which ribosomal RNA had been labelled in advance no evidence of such an association was seen. It seems most likely that synthesis of 26 S RNA is an integral part of virus replication. Early in infection (before 3 h), 26 S RNA is the chief component; thereafter the amount

of 26 S RNA relative to 45 S RNA decreases as infection proceeds (Fig. 4). With brief labelling periods at the time of maximum RNA synthesis radioactivity appears in the 26 S component in advance of 45 S RNA (ref. 7). For example, with a labelling period of 15 min at 5 h after infection, 86 per cent of the radioactivity was distributed in the 20–26 S region of the gradient; this was decreased to 79 per cent with a labelling period of 30 min and to 49 per cent after exposing infected cells to the labelled precursor for 1 h. Even when corrections are made for the ribonuclease resistant RNA component the ratio of radioactivity in the ribonuclease sensitive 26 S RNA to that in the 45 S component still decreases as the time of exposure to the labelled precursor is increased.

RNA with characteristics similar to SFV 26 S RNA has been described in hamster kidney cells infected with foot-and-mouth disease virus<sup>2</sup>, in encephalomyocarditis (EMC) virus infected ascites tumour cells<sup>4</sup>, and in *Escherichia coli* infected with MS 2 phage<sup>3</sup>. Thus it would seem that the formation of this class of RNA is not peculiar to the growth of SFV in CEF. Kelly *et al.*<sup>3</sup> have suggested that 20 S RNA in MS 2 infected *E. coli*, analogous to 26 S SFV RNA, is similar to progeny viral RNA but in the form of a random coil. The sedimentation of SFV RNA (45 S) in sucrose gradients containing 0.1 molar potassium chloride is more rapid than that of EMC viral RNA (37 S), although under identical conditions the double stranded RNA forms of both viruses sediment at approximately the same position (20 S); this would suggest that the RNAs of these viruses have molecular weights of the same order— $2 \times 10^6$  for EMC virus RNA—but that the 45 S SFV RNA may possess a more compact configuration. If these two RNAs differ only in their configurational states, however, then the difference must be a radical one to account for the variance in sedimentation velocities. If the 45 S RNA were circular, possibly through the overlapping of short segments at the ends of the molecule, it would account for the difference. Alternatively, the compactness of the 45 S form may be caused by a low molecular weight component (for example, a polyamine) which is stabilizing the configuration.

Whatever the nature of the structural differences the data on the relative rates of precursor incorporation into the two forms suggests that 26 S RNA is a precursor of 45 S RNA, and that 26 S RNA may be the form in which viral RNA is released from the RNA polymerase. Transition to the 45 S form may occur during incorporation of the RNA into the virus particle; the compact configuration may be imposed on it by the structural proteins of the virus. In addition to serving as a precursor, 26 S RNA could have other functions. For example, it may be in this form that viral RNA acts

as a messenger in the synthesis of viral proteins, or as a template for the viral RNA polymerase.

It should be pointed out that these suggestions need not necessarily apply to other RNA viruses; formation of 26 S RNA may occur as a result of the particular structural characteristics of the viral RNA. There is evidence that Sindbis virus, which is related to SFV, has a high degree of secondary structure compared with poliovirus RNA (ref. 11), and it may be significant that 26 S RNA is such a prominent component of cells infected with SFV compared with other systems.

Since this article was submitted for publication Friedman *et al.* have shown that CEF infected with SFV contain three distinct RNA species similar to those described here. (Friedman, R. M., Levy, H. B., and Carter, W. B., *Proc. U.S. Nat. Acad. Sci.*, **56**, 440; 1966.)

We have now analysed RNA from purified virus and from cells infected with SFV for their base compositions. This was done by incubating actinomycin-treated infected cells with phosphorus-32 for 7 h after infecting and extracting RNA both from cells and extracellular virus (after purification). The RNA preparations were sedimented through sucrose gradients and fractions at the peaks of the 45 S and 26 S regions pooled and hydrolysed with potassium hydroxide. The proportion of radioactivity in each nucleotide was measured after column chromatography according to the method of Katz and Comb<sup>12</sup>. The percentages of adenylic, cytidylic, guanylic and uridylic acids, respectively, in each of the RNAs were as follows: purified virus RNA (mean of duplicates), 27.4, 24.4, 26.1 and 22.2; 45 S RNA taken from infected cells (four determinations),  $27.5 \pm 0.7$ ,  $24.3 \pm 0.7$ ,  $26.2 \pm 0.6$  and  $22.0 \pm 0.5$ ; 26 S RNA from infected cells (four determinations),  $28.0 \pm 0.4$ ,  $24.5 \pm 0.6$ ,  $26.0 \pm 0.4$  and  $21.5 \pm 0.4$ . It therefore seems that the base composition of 26 S RNA does not differ significantly from that of 45 S RNA, which supports our suggestions that these two RNAs may be different configurations of the same molecular species.

## Mechanism of the Insect Ear

by

P. E. HOWSE

Department of Zoology, University College, Cardiff

The similarity of the responses and structures of the tympanal organ and an organ in the leg of insects suggests that the former responds to acceleration that induces transient oscillations of the sensory cells.

It was first noted in 1939 that responses could be recorded in the tympanal nerve of *Locusta migratoria* which were synchronous with the amplitude modulation pattern of sounds<sup>1</sup>. It is a general feature of insect tympanal organs that they respond to amplitude modulation and it has been suggested that the species specificity of insect songs lies in the frequency of modulation. Certainly, the songs of insects with tympanal organs are characterized by rapid amplitude modulation, amounting in some cases to pulse modulation.

An intensive investigation of the efficiency of different kinds of amplitude modulation in producing behavioural responses ("phonoresponses") in certain Orthoptera<sup>2</sup> gave results which suggested that "transients" were the essential features of sounds to which the tympanal organs were responsive. There is a basis for confusion here, because transients are normally defined as "phenomena which take place in a system owing to a sudden change in conditions and which persist for a relatively short time after the change has occurred" (British Standards Institution).

They thus involve complex changes in frequency and amplitude. Busnel<sup>2</sup>, however, defines a transient as "a quick rise from intensity zero to maximum intensity or reversed".

Haskell<sup>3</sup> has disputed the important role ascribed to transients by the French school, and in an electrophysiological study of the responses of certain Acrididae to natural and artificial stridulation concluded that the modulation frequency was the only feature of the sound that produced predictable responses in the tympanal organs. Transients (as defined by Busnel) in recordings of natural stridulation produced variable responses.

Autrum<sup>4</sup>, in an electrophysiological investigation of the responses of the tympanal organ of *Tettigonia viridissima*, confirmed that the steepness of modulation, or the rise time, was an important factor in the detection of sound. It was established that constant unmodulated sound of high frequency elicited responses in the tympanal organ of insects. Autrum established that there were two kinds of response: a phasic response, with a relatively short latency, to transients with amplitude changes of sufficient steepness; and a tonic response, with a relatively long latency, to constant tones.

Autrum<sup>5,6</sup> also established that the insect sub-genual organ responded to substratum vibration, and held that vibration of the tibia caused vortices in the blood around the organ, which triggered off activity of the sensory cells. I have investigated the sub-genual organs of the termite and cockroach<sup>7,8</sup>, and found that the electrical responses of the organ to vibration of the leg were similar in many respects to those obtained from tympanal organs in response to airborne sound. With consideration of the structure of the organ and tests on a model, a new theory of the mode of action of the organ was proposed, which can now be elaborated. The same theory would also seem to be applicable to the insect tympanal organ.

A recent examination of the sub-genual organ of the cockroach *in situ*, stained intravitaly with methylene blue, has revealed some features that are not evident in sectioned material. An essential part of the organ is a leaf-like membranous structure attached to the wall of the leg at one end and to the trachea at the other (Fig. 1). This membrane is covered with accessory cells, and is thought to consist of processes derived from them. Sensory scolopale units\* are attached by their tips to the accessory cells. It may be noted that the sub-genual organ of the termite has been described and has a similar structure<sup>9</sup>.

It appears that a sudden displacement of the leg will result in a displacement of the membrane relative to the cuticle. It seems to be a general feature of the insect sub-genual organ that it is anchored to a constricted portion of the trachea (Fig. 1). This means that there is a discontinuity in the structure of the trachea, which will therefore be less resistant to deforming forces acting at this point along the main axis of the trachea. Thus the membrane of the sub-genual organ would appear to be effectively fixed at one end (to the leg wall), and capable of movement at the other; elastic restoring forces are supplied by the trachea. The membrane itself presumably has some elasticity so that it will tend to oscillate in response to a sudden displacement of the tibia. Damping forces will be supplied by the blood in the haemocoel. The same will apply again to each scolopale unit, which is hinged distally, damped by the blood, and subject to elastic restoring forces from the nerve fibre which suspends it.

Electrophysiology has shown that the sub-genual organ of the cockroach generally responds only to the onset of a suitable stimulus or to a sudden disturbance in steady state conditions produced by the stimulus<sup>8</sup>. It was therefore suggested that the receptor responded when it, or some part of it, was set vibrating at a natural (resonant) frequency by a sudden acceleration of the tibia. There appear, theoretically, to be three possible conditions under

which excitation of the sub-genual organ of the cockroach could occur, when: (a) the membrane is in natural oscillation; (b) the scolopale units are in natural oscillation; and (c) both are in natural oscillation at the same time. The last possibility is the only one consistent with the electrophysiological findings, for in the other cases a continuous discharge from the sensilla would be expected at frequencies of stimulation at and around the natural frequency. It can therefore be assumed that a sudden acceleration of the tibia will set the membrane of the sub-genual organ oscillating at its natural frequency, which in turn will cause the scolopale units to oscillate at their natural frequencies. To fit the explanation, it must be assumed that the two natural frequencies are different, which appears evident from the relationships of the structures concerned, so that shear forces will be produced between the two. After the transient natural oscillations have died out the organ will vibrate at the same frequency as the leg, giving rise to a new steady state.

The tympanal organ of the insect is essentially analogous in structure to the sub-genual organ, having a surface that transmits forced vibrations (the tympanum) to which are attached accessory cells, often elongated, to which scolopale units are attached by their tips. If the mode of action of the tympanal organ is similar to that of the sub-genual organ the following characteristics of response are to be expected.

(1) The threshold curves for the tympanal organ should have a shape similar to those typical of the sub-genual organ and suggestive of resonance phenomena. This is well known to be generally true.

(2) If the tympanal organ is an acceleration receptor the optimal threshold displacements for different organs should be inversely proportional to the square of their optimal frequencies. This is seen to be so in the values in the table compiled by Schwartzkopff<sup>10</sup>. A plot of the logarithms of optimal frequencies against optimal threshold intensities gives a regression coefficient of  $-0.62$  ( $P < 0.01$ ).

(3) There should be nervous responses to sudden changes in steady state conditions. These changes could be either in the form of amplitude modulation or "transients" in the sense used by Busnel and his co-workers. The change should impart an acceleration to the sense organ and the minimum acceleration necessary would be defined by the threshold curve. There should be synchronous responses to sound of up to a certain frequency, representing the maximum modulation frequency, providing that the acceleration imparted in each cycle is above the threshold value.

Fig. 1. Diagram of the sub-genual organ of *Periplaneta americana*.

\* The scolopidium minus its accessory cell is referred to here as the scolopale unit.

(4) There should be rapid "adaptation" to a tone of high frequency if the amplitude and frequency are kept constant. There would therefore be a "phasic response" or "on effect". Tympanal organs, however, are clearly very lightly damped systems compared with sub-genual organs and the possibility arises that sound around the optimal frequency would set up strong resonant vibrations of the accessory cells which would be strong enough to keep the scolopale units in continuous vibration, giving rise to a "tonic response". (It is known that substratum vibration of high intensity will sometimes provoke a tonic response in the sub-genual organ<sup>8</sup>.) It follows that the tonic response, although deriving from the same sensilla, would have a longer latency because of the time taken for the build-up of resonance.

(5) At a fixed frequency the rate of production of nerve impulses should be related to the square root of sound intensity, or to the amplitude of displacement of the tympanic membrane, because intensity is equal to  $ka^2f^2$ , where  $k$  is a constant,  $a$  the amplitude and  $f$  the frequency. A limit will be imposed by the non-linear elasticity of the tympanic membrane.

(6) An after discharge should follow a very brief stimulus, and the length of the after discharge reflects the duration of the natural oscillation of the scolopale cells and, therefore, it is proportional to the square root of the sound intensity. It can easily be shown that  $A/A' = t/t'$ , where  $A$  and  $A'$  are initial amplitudes of natural vibration and  $t$  and  $t'$  the respective times required for the vibrations to die down to a given level. An after discharge might also follow the sudden cessation of a constant stimulus because the energy released would result in a free oscillation. This is a special case of (3).

(7) The latency of the response to a harmonic stimulus should vary inversely with (frequency)<sup>2</sup> if the amplitude is kept constant, or inversely with intensity if the frequency is kept constant. This is because the threshold acceleration in a harmonic stimulus will be attained earlier as its frequency or amplitude is increased.

It will be recognized that these are all typical characteristics of the responses of tympanal organs and are illustrated particularly well in orthopteran and lepidopteran tympanal organs, for example, in *Tettigonia viridissima* studied by Autrum and in the tympanal organ of the moth *Prodenia eridania* investigated by Roeder and his co-workers<sup>11</sup>. It is significant in the latter case that touching the sensilla with a fine probe, which would damp any natural vibration, abolished the response to sound.

If the theory proposed here is accepted it is clear that the practice of referring to the tympanal organ as a displacement receptor as opposed to a pressure receptor, while correct, is misleading. It appears that the organ is a pressure gradient receptor<sup>5</sup>, that is, an acceleration receptor. Transients are seen as special cases of amplitude modulation as indeed they are accepted to be, and the importance of a short rise time in provoking responses in the tympanal organ is then clear, because the shorter the

rise time the greater the acceleration imparted to the tympanum. This is not to say that other features of modulation of a sound would not affect the perception of a transient there. Frequency modulations involving the order of change of acceleration we are considering are probably rare in nature and would be difficult to achieve without simultaneous changes in amplitude. Detection of changes in frequency would, however, be possible in some form if sensilla of graded sizes, and therefore differing natural frequencies, were present in a receptor. It is then possible that there is a "typical intensity" of a sound of a certain frequency, which results in the stimulation of a certain proportion of all sensilla, because the optimal and natural frequencies may be equated, and the higher the optimal frequency the lower the threshold at this frequency (see note 2). Sound of greater or lesser intensity would activate more or less sensilla. Evidence for a typical intensity is found in the work of Busnel and Loher<sup>12</sup>, who found an increase in phonoresponses in *Chorthippus brunneus* to sounds up to a certain intensity, after which there was a falling off in the number of responses. At 85 dB with a time rise of 2 msec they found a maximum of 45 per cent positive responses, but only 9.5 per cent at 100 dB. The same sort of condition could arise with a shift in the frequency of a sound stimulus with constant amplitude, and this would explain very well certain unexpected findings. In the tettigoniid *Gampsocleis buergeri* Katsuki and Suga<sup>13,14</sup> found an increase to a maximum in impulse frequency in central neurones and then a decline as the frequency of sound was increased at constant intensity. They found evidence for the existence of two groups of neurones. Those of one group were activated only by sound of higher frequencies, and were more sensitive to stimuli than those of the other group which were activated by sounds of lower frequencies. Horridge<sup>15</sup>, studying *Locusta migratoria*, *Schistocerca gregaria* and *Acheta domesticus*, also found evidence for two different groups of receptors, sensitive to higher and lower frequencies, and showed that the discrimination took place at the level of the sense organ.

I thank Dr. J. G. Thomas, of the Department of Electrical Engineering of this College, for invaluable criticisms.

## Origin of Eyes and Brains

by

R. L. GREGORY

Psychological Laboratory, Cambridge

The evolution of the mechanism of visual perception must entail the separate elaboration of eyes and brain. But which came first? Or is this a "hen and egg" problem?

ALL knowledge comes through the senses, and this suggests an intimate link between the evolutionary development of brains and eyes. Somehow brains and eyes are developed by the random steps which form the evolutionary ladder according to the dictates of survival value at each rung.

The restraints imposed on the development of perception by natural selection give some clue as to the way in which eyes and brains came into being. The fossil record is of no use in tracing the origins of these organs because the crucial steps have not been preserved. An attempt

may, however, be made to put existing "primitive" forms into sequence according to various criteria. I shall not attempt a detailed account but rather endeavour to outline how the principal forms of eye could have come about and consider the "hen and egg" problem: which came first—the eye or the brain?

"Simple" eyes have a single optical system serving many photoreceptors. "Compound" eyes, found in arthropods, have up to many thousand individual optical systems, each with its own photoreceptor. Both kinds of eye must have appropriate neural systems to handle the information they provide. There is then a "hen and egg" problem, for it is very difficult to imagine how an eye could develop unless there were some suitable neural system already present to handle its information. Why, however, should a visual "computer" arise before there was an eye to feed it with information? If there is an answer to this, there is then the question of why there should be the two great classes of eyes.

Animals live in a world of objects, some edible, others dangerous, some protecting, such as crevices in rock, and others irrelevant to their survival. Objects have many characteristics beyond shape and colour, which alone are represented by optical images. It is these other characteristics which are biologically important. One cannot be attacked and eaten by an image—hence the vicarious pleasures of the cinema—and neither can one feed on images. It follows that information given by eyes is only of indirect use to living creatures, and to make any use of visual information considerable computing is required. Other senses, especially touch and taste, do, however, give information of immediate value and thus it can be assumed with some confidence that these senses were the first to develop. Touch and the chemical senses directly monitor biologically vital features of the environment, and their information requires but a minimal "computer". It is therefore reasonable to suppose that vision is a lately acquired sense. How did it arise? How did a neural computer develop which was capable of reading significance into the non-biologically important optical images? The problem is especially acute because the significance of the images is not in the present state of affairs, but rather in what they presage of the immediate future. Touch and the chemical senses signal the state of the environment in immediate contact with their owner, but vision signals distant events, and may give warning of the future. The visual computer cannot be a simple reflex affair, which acts as soon as possible to a "stimulus". It must transform optical information into hypotheses of the nature of distant objects, which may be friend or foe, food or disaster. The eyes give time to compute; they allow brains to devise strategies more subtle than reflexes in response to stimuli.

*Origin of the simple eye.* The first eyes<sup>1,2</sup> were merely regions of the outer skin which were sensitive to light, perhaps originally responding more to heat than to light. These first light-sensitive regions could have fed the original touch neural systems. Simple tropisms and immediate reflex action to photic stimuli could have been mediated by the touch neural system. It is not too difficult to imagine a gradual improvement in the sensitivity to light and that certain cells became specialized photoreceptors in regions where they would be most useful. The ends of the animal were favoured with the first true eyes—gradually deepening pits lined with specialized cells sensitive to light. The pits served to increase the contrast of shadows, reducing ambient light like the shafts dug in the ground by ancient astronomers to view stars in day-time. Plato describes how Thales fell down such a pit; obviously he should have covered his pit to prevent such accidents. It seems that the eye pits of primitive creatures did develop such protective covers—in the form of transparent windows—to prevent blockage by alien bodies, such as particles in suspension and grains of sand. It is usually held that these windows gradually thickened

towards their centres, for this would increase the intensity of light at the bottom of the eye pits. From such a process a lens would have evolved, and thus give true formation of images. With improvement in the resolution of the lens the acuity would increase to match it, transforming skin which was sensitive to touch into a true retina. The optical reversal of the lens must have imposed the biggest jolt since life began, for the ancient touch inputs were suddenly reversed, evidently requiring the dramatic reorganization of the nervous system which we see today in the crossings of the chiasma. Retinal information is different from the information gained from touch, for not only is the pattern reversed but also it refers to distant objects. The crossings of the chiasma probably served to relate the reversed retinal patterns to touch information from the body<sup>1,3</sup>. Primate perceptual systems can compensate for systematic translations of their retinal images<sup>4,5</sup>, but there is no evidence of this ability in creatures as advanced as even the amphibians<sup>6</sup>, and so explicit reconnection seems to have been necessary at the early stages of perception. The retinal image is not only reversed: it shrinks as represented objects become more distant. It seems that this is compensated by scaling mechanisms, which give size constancy<sup>7</sup>, to maintain an effective connexion between the neural representations of touch and vision despite changing image size.

Fig. 1. An early compound eye of a trilobite from the Cambrian.

*Origin of compound eyes.* Each unit, or ommatidium, of a compound eye consists of three basic elements: the corneal lens, crystalline cone and the photoreceptor, or rhabdomere. Compound eyes are found in early fossils, in trilobites from the lower Cambrian rocks of about 600 million years ago (Fig. 1). They appear to be essentially the same as modern insect eyes, but because there are no earlier examples in the fossil record it is only possible to guess at the earlier stages, using living creatures as examples of what has occurred, however uncertain the order may be. There is a special difficulty with the compound eye: what could give rise to many separate and identical elements, each complete with lens and photoreceptor? It is difficult enough to imagine how the simple eye developed—but how could several hundred, all at once? A single element would seem quite pointless—or is it?

I have supposed that the simple eye took over existing touch neural mechanisms, and will later point out that there are basic reasons for supposing that touch information was essential for the first vision. There are two kinds of touch, which involve entirely different neural mechanisms. These are skin pattern touch and limb probe touch. Pattern touch involves the reception of patterns by contact with areas of skin, while probe touch is very different and

requires exploratory movements of a limb. Pattern touch gives information only of structures lying on the two dimensional surface of the skin, while probe touch gives information in three dimensions, within the reach of the limb. Pattern touch is mediated by many parallel neural channels simultaneously sending pattern information to the central nervous system; active touch is essentially single channel, signalling structure in three dimensions but spread out in time as the probe explores external space. The neural systems for the two kinds of touch must always have been very different; one requires many parallel channels, the other a single channel transmitting information of space traced in time.

If the first retinal images were accepted by the original nervous system responsible for pattern touch, could the compound eye be a multiplication of a single moving element, signalling down a single channel to explore space in a manner similar to probe touch?

An example exists of a living creature in which a single unit eye seems to work as a photic probe. Exner<sup>8</sup> described a small copepod, *Copilia*, living in the bay of Naples. He described that it has a pair of strange eyes, like telescopes with two lenses; the second "eye piece" lens is deep in the body, and in "continual lively motion". We have examined living specimens, and it appears that these eyes could be single channel scanning probes<sup>9,10</sup>.

Fig. 2. Photograph of a single channel scanning eye of *Copilia quadrata*.

The female of *Copilia quadrata* is 4-5 mm long, 1 mm wide, and entirely transparent; there is no colouring except for an orange pigment which surrounds the single photoreceptors of each eye. Under the microscope the internal structure of *Copilia* is clearly visible, including that of the eyes and the optic nerve. The two eyes occur on opposite sides of the animal, which has an unusual shape for a copepod because it is very wide at its anterior. There are two large lenses placed far apart in front. Each eye has a large anterior lens and a second posterior smaller lens which is shaped like a pear. Almost half the total volume of the animal is taken up by the two eyes. Attached to the posterior lens, which is situated deep in

the body of the animal, is a long orange pigmented structure which extends back from it and curves inward, but does not touch its counterpart from the other eye. The posterior lens is situated at the image plane of the large anterior lens, and moves horizontally across the image plane of the first lens with a "saw-tooth" scan. The "scanning" rate varies from about one scan/2 sec to about five scans/sec. The movements are synchronized; the posterior lens and photoreceptor of each approach and recede together. In the resting position the optical units are separated from each other, near the tough transparent outer cuticle of the creature, from which position they rapidly approach each other and then slowly separate across the image planes of their respective anterior lenses.

The optic nerve arises from about half way down the pigmented photoreceptor, and enters the brain which is located at the centre of the creature. *Copilia* has very simple mouth parts and, because it is a filter-feeder, does not have to seek its "prey". It is almost certain that sexual reproduction occurs; obviously this requires recognition of the male. It is not known, however, what use *Copilia* makes of its eyes; however, it does seem clear that each eye is an optical unit, which works by temporal scanning somewhat like a simple television camera. Detailed examination reveals that the elements of the eye are extremely similar to corresponding elements of an ommatidium of a modern compound eye. The spacings between the anterior and posterior lenses, however, are quite different—distant in *Copilia* but almost touching in normal compound eyes. The lenses themselves and the single "rod" photoreceptors, however, are almost identical.

*Copilia* could be a surviving form with a prototype single channel scanning eye. The compound eye could have developed by multiplication of these units. It seems easier to suppose this than that a hundred or a thousand units sprang up together. Why should the prototype single element scanning eye not develop further, but rather multiply to form the compound eye? The answer to this seems fairly clear—the basic engineering limitation of scanning systems is the amount of information which they can transmit by the single channel. The channel capacity of any nerve fibre found in nature is extremely low compared with electronic channels; at best, the maximum frequency response approaches only  $10^3$  pulses/second; while, for comparison, to transmit television pictures about  $4 \times 10^6$  cycles/second are needed. Sophisticated perceptual systems save channel capacity by various tricks<sup>11</sup>, but a vast discrepancy still remains. If, however, a scanning eye were duplicated, the elements could send down information simultaneously. This would be rather like exploring a structure with two fingers at once. There could be three fingers, four fingers . . . a thousand fingers or ommatidia. There is no need to sweep the eye of a thousand optical units across the structure, for the entire pattern can be signalled by simultaneous transmission down the many channels. Then scanning can be abandoned. The compound eye started by using a single channel, with the kind of temporal information processing of probe touch, but it can be supposed to have developed many static parallel units, to become, like the simple eye based on the pattern touch neural system, a mosaic eye. Compound eyes which have too few elements to have entirely abandoned scanning (or active exploration) by each photic probe are still found. In *Daphnia* (Fig. 3) we find a compound eye which consists of about twenty elements, and this eye is in continuous oscillatory movement. This seems to be an eye which is part-way up the sequence from the single channel scanning eye of *Copilia* to the fully developed static compound eye. In *Daphnia*, there are few units and it seems that the deficiency is made up by oscillatory scanning very like the single unit eye of *Copilia*. All compound eyes with but few elements can be assumed to scan.

I have outlined, in general terms, a possible sequence of events leading to simple and to compound eyes. Each must have taken over and developed for its own use the primordial neural mechanisms mediating touch. The simple eye took over the pattern touch system; the prototype scanning unit, which later formed compound eyes by multiplication, took over probe touch neural mechanisms. By supposing that already existing touch mechanisms were taken over for vision, the "hen and egg" problem of which came first, eye or brain, is answered. There is some justification for supposing that the first eyes took over earlier touch neural systems, which then developed to process distant information. Jumping a thousand million years or so, there may be other and deeper reasons for believing this.

Fig. 3. Photograph of the eye of *Daphnia*; possibly a scanning eye.

*Origin of visual perception.* What are the essential differences between perception in primitive creatures and in higher animals, including man? It is generally believed that all primitive perception is a matter of reflex neural mechanisms, activated by more or less specific "stimuli". Perceptual learning is certainly minimal in primitive creatures; and these special visual patterns can be supposed to have taken on significance through ancestral disasters just as in the development and inheritance of more obvious structural characteristics through natural selection. Some insects do show visual learning (for example, bees learn key features of the terrain around their nests for navigation) but this ability is much greater in mammals, especially primates. Clearly perception, as it developed phylogenetically, became less and less tied to specific visual patterns, so that finally a large variety of patterns elicit the same behaviour. We may say that perception becomes geared to the response to objects, no matter how they are presented to the senses. Finally, retinal images become indicators, symbols, identifying objects. What happens is that we perceive far more than is actually sensed in each moment of perception. We "see" that a table is hard, and a chair safe to sit on. We "see"

from a smile that a person is pleased. This goes far beyond the given sensory data and yet it is usually correct. This ability of the human perceptual system to go beyond immediate data is brought out most dramatically by considering cartoons<sup>10</sup>. A few lines convey an entire story with the personality of each person and his mood. It is useful to think of perceptions as hypotheses based on, but certainly not limited by, current sensory data.

When visual information leads to behaviour appropriate to non-visual features (such as the hardness of a table, though the image of the table is not hard), then the retinal image is acting as a sign. Retinal images are symbols, like words in a language; however, like any other symbols there must be a process of initial association to acquire significance, or the symbols are in a logical vacuum and cannot represent any reality. Furthermore, retinal images are but flat projections of a three dimensional world and yet they give perception of three dimensions. There must be direct, non-visual, information of the third dimension. Other information comes from touch. It appears that any conceivable device for perceiving which relies on two dimensional images must use, at some stage, direct touch information if it is to interpret its images in terms of the three dimensions of surrounding space.

Dependence on early touch experience for visual perception is supported by cases of recovery from congenital and early blindness<sup>12,13</sup>, and in animals reared in the dark<sup>14,15</sup>. What is true for development of perception in the individual should also be essentially true for the development of vision in evolution, for touch must have preceded vision if touch information is required to make retinal images effective symbols of the non-optical world of objects.

If simultaneous information from the eyes and from touch is required to develop correlations between them, regions of the body which could not be seen could not give correlations. Held and Hein, in an address to the Congress of Psychology in Moscow, have shown that a monkey which is denied the sight of one of its fore limbs does not develop normal eye-limb co-ordination, though the other limb is normal. It is the fore limbs, and especially their movements, which are available to vision but not pattern touch—which is hidden from the eye by (non-transparent) objects in contact with the skin. It is active rather than passive limb movement which gives visual learning<sup>16</sup>.

In the human being we see preserved almost all the stages in the developments of vision from the simplest reflex (closing of the eyes on sudden change of illumination), to pattern recognition, and identification of objects from unusual points of view, with prediction of the immediate future based on the past. Such feats cannot be simulated with even the most advanced computers.

## Gravitational Red-shifts in Quasi-stellar Objects

It has already been pointed out that the very large energies,  $\sim 10^{60}$  erg or more, associated with some radio sources imply the existence of supermassive objects and strong gravitational fields<sup>1,2</sup>. The subsequent discovery of large red-shifts associated with quasi-stellar objects<sup>3-6</sup> might well have been taken as confirming the existence of such strong fields. Greenstein and Schmidt<sup>7</sup>, however, gave an argument to show that the observed large red-shifts are not of gravitational origin, and this argument has generally been thought to demonstrate the cosmological nature of the quasars. The purpose of this communication is to argue that, while the conclusion of Greenstein and Schmidt<sup>7</sup> is correct for their assumed model, a different model can be postulated, one which permits a gravitational explanation for the red-shifts of the quasars.

The unusual picture of gravitational reddening is that quanta emitted from the surface of an object of mass  $M$  and radius  $R$  experience a wavelength shift given by  $\Delta\lambda/\lambda_0 = z = (1 - 2GM/Rc^2)^{-1/2} - 1$ . Apart from the difficulties discussed by Greenstein and Schmidt<sup>7</sup>, there is the further difficulty in this picture that even the maximum permissible value of  $z$  is still not adequate to explain the observations. For a perfect fluid, the well known Schwarzschild interior solution gives  $z_{\max} = 2$ . The perfect fluid case is unreal, however, in that the transmission velocity within the fluid exceeds the speed of light. An analysis by Bondi<sup>8</sup> leads to the conclusion that, if appropriate conditions on stability and on the equation of state are imposed,  $z_{\max}$  cannot exceed about 0.62. Yet values of  $z$  somewhat in excess of 2 have been observed<sup>9-11</sup>.

We propose that the model be changed to one in which the observed emission lines come from the centre of an object, not from its surface. Instead of the system comprising a single coherent cloud of gas, we imagine a large number of comparatively compact subunits with radii  $\ll R$ , the probability for an arbitrary direction through the centre intersecting any of the subunits being small. As an example of the kind of structure we have in mind, we could equate the subunits to clusters of neutron stars or other highly collapsed objects. We could take  $M = 10^{12} - 10^{13} M_{\odot}$ ,  $R = 10^{18} - 10^{19}$  cm, in which case the probability of an arbitrary direction from the centre intersecting a star is  $\ll 1$ . If the cloud at the centre has radius  $\sim 10^{16} - 10^{17}$  cm, say, light emitted by it passes essentially freely through the star distribution. In this new model the main mass serves to generate a strong gravitational field. Continuum emission is taken to be of non-thermal origin (although faint stars could make a contribution in the near infra-red) while emission lines come from the gas cloud at the centre.

The numerical values for  $R$ ,  $M$ , and for the radius of the central cloud, can be changed from those already mentioned. The foregoing values seem to accord with the observed properties of quasars, but the model is evidently not critically dependent on these particular values.

The gas cloud at the centre lies at the bottom of a gravitational potential well. Writing the metric in the form

$$ds^2 = c^2 e^{\nu} dt^2 - e^{\lambda} dr^2 - r^2 d\Omega^2 \quad (1)$$

$e^{\nu}$  is effectively constant throughout the cloud. Emission lines from the cloud are red-shifted by  $1 + z_c = e^{-\nu/2}$  where the subscript  $c$  denotes central values. The immediate advantages of the present model are that (a) gas naturally tends to fall to the centre of the system, and (b) the whole central gas cloud is subject to the same red-shift. Because of (b), emission lines from the cloud are not smeared out, as they would be in the model considered by Greenstein and Schmidt<sup>7</sup>.

There is a third important advantage. The red-shift  $z_c$  from the centre can be much larger than the shift  $z_s$  associated with emission from the surface. For example, we have

$$\frac{1 + z_c}{1 + z_s} = \frac{2}{2 - z_s} \quad (2)$$

in the Schwarzschild interior solution. In the limiting case in which the central pressure  $\rightarrow \infty$ ,  $z_s \rightarrow 2$ , so that  $z_c \rightarrow \infty$ . This property is general for all static structures. For a given  $M$ , and for a simple equation of state,  $p = p(\rho)$ , there is an infinity of equilibrium solutions corresponding to different choices for  $R$ . As  $R$  decreases,  $p_c$  increases until  $p_c \rightarrow \infty$  for a certain  $R$ , when  $z_c$  also  $\rightarrow \infty$ . A distribution of subunits, star clusters, for example, will in general have a more complicated "equation of state" than this, but the same property must hold. As a further explicit example, in the "standard model" studied by Tooper<sup>12</sup>

$$\frac{1 + z_c}{1 + z_s} = (1 + f\alpha)^{4/f} \quad (3)$$

Here  $f$  is a number satisfying the inequalities  $2.5 \leq f \leq 4$  and  $\alpha$  is proportional to the central value of the ratio of the pressure to the baryon number density. The limiting case for such a model occurs when  $\alpha \rightarrow \infty$ , in which case  $z_c$  again  $\rightarrow \infty$ .

Radiation pressure does not play a critically important part in the study of static stellar atmospheres because gravity and radiation pressure which act on an ion depend similarly on the radial co-ordinate, so that radiation pressure cannot come into adjustment with gravity through a change of  $r$ . The situation is different in the present case, however. For ions outside the central gas cloud, radiation pressure decreases with  $r$ , whereas gravity increases with  $r$ , provided  $r$  does not become too large. (For a stationary particle in the metric (1) the radial acceleration  $d^2r/ds^2 = -\frac{1}{2}e^{-\lambda}dv/dr$ , which increases in magnitude with  $r$  because  $dv/dr = 0$  at the centre. Eventually, the acceleration falls off as  $r$  continues to increase.) This means that stable equilibrium positions are possible in principle for clouds of ions that surround the central cloud. It is possible that the absorption lines found in several quasars arise from such floating ion clouds. This suggestion would require  $z$  for absorption lines to be less than  $z$  for emission lines—at any rate for a static ion cloud. It also suggests that  $z$  may be different for different ions. Motions of the ion clouds or departures from spherical symmetry will lead to other observational possibilities.

The value  $M = 10^{12} - 10^{13} M_{\odot}$  mentioned previously would accord with the possibility that quasars may give rise to galaxies, or even to whole clusters of galaxies. For the usually accepted mean intergalactic density of about  $10^{-28}$  g cm<sup>3</sup> the total mass within 100 Mpc is about  $10^{18} M_{\odot}$ . Most of this mass is unaccounted for—the galaxies which are spread uniformly throughout space give about  $3 \times 10^{-31}$  g cm<sup>3</sup>. If the "missing mass" were condensed entirely in quasars of mass as large as  $10^{13} M_{\odot}$  there would still be about  $10^5$  quasars within 100 Mpc.

A further consequence of the proposed model is that a simple magnitude-red-shift relation for quasars such as that derived on cosmological grounds, for example, would not necessarily be expected.

### Possible Large-scale Clustering of Quasars

Strittmatter, Faulkner and Walmesley<sup>1</sup> have recently pointed out that quasars with large red-shifts do not appear to be distributed isotropically. The quasars with red-shift  $z > 1.5$  are mainly confined to two regions, one near the North Galactic Pole and the other in the South Galactic Hemisphere. These groups each have an angular diameter of about  $30^\circ$ . Quasars with intermediate  $z$  also appear to be distributed anisotropically, but with a larger angular diameter. Strittmatter, Faulkner and Walmesley have suggested that, if future observations confirm these trends, then either (a) the universe is anisotropic for  $z \geq 1$ , or (b) quasars are not at cosmological distances.

We would like to propose a third possibility (c) that the universe is inhomogeneous on a scale corresponding to  $z \sim 1$ . This seems more plausible than anisotropy because the radio sources in the 4C catalogue are distributed isotropically<sup>2</sup>, and the excess microwave background<sup>3-5</sup> which probably comes from regions with  $z \gg 1$  (ref. 6), appears to be highly isotropic. (A value of 3 per cent is quoted by K. S. Thorne in a communication to be published in the *Astrophysical Journal*.) Moreover, the existence of large scale inhomogeneities is compatible with an overall isotropic, homogeneous point source model of the universe.

We assume that the universe now contains regions of dimensions  $R \sim 1,500$  Mpc in which the density exceeds that outside by the factor  $x$ . If the higher density facilitates the formation of quasars, prolongs their life-time, or increases their intrinsic radio luminosity, then the number of quasars per unit volume with a given limiting radio flux density will be higher inside clusters, by a factor, say,  $x^n$  ( $n > 1$ ). If  $n$  is large, a correspondingly smaller value of  $x$  yields a given clustering of quasars. An upper limit on  $n$  is, however, set by the observed log  $N$ -log  $S$  relation for quasars<sup>7-10</sup>. Following Davidson and Davies<sup>7</sup> and Longair<sup>8</sup> we find that  $n \leq 3$ . A detailed discussion would not be justified but for illustration we take  $x \sim 3$  and  $n \sim 2$ . Then if clusters occupy about one-third of space, they would contain more than 80 per cent of all quasars.

We must also avoid excessive anisotropy in the effective temperature  $T'$  of the microwave background. We would

expect  $\frac{\delta T'}{T'} \sim \frac{G \delta M}{c^2 R}$  (ref. 11), where  $\delta M$  is the excess mass

in a cluster. We find that, if  $\frac{\delta T'}{T'} \leq 3$  per cent, the present mean density  $\rho \leq 10^{-30}$  g/c.c. (for  $x \sim 3$ ). This is consistent with the observed lower limit of  $3 \times 10^{-31}$  g/c.c.<sup>12,13</sup> and implies a small deceleration parameter  $q_0 (\leq 0.025$  if the

cosmical constant is zero). Such a low density universe would be consistent with the observed lack of absorption on the short wavelength side of Lyman  $\alpha$  in the spectra of quasars with  $z \sim 2$  (refs. 14-18), since any intergalactic gas present would be ionized by ultra-violet radiation from quasars<sup>15,19</sup>. Furthermore, a low density universe can be more easily reconciled with the observed X-ray background at 3-8 Å (refs. 20-24), and with the low helium abundance in certain old stars<sup>24-29</sup>.

Since quasars of low  $z$  occupy a large region of the sky, it is likely that we are inside a cluster. These quasars are, however, more numerous, relative to quasars of high  $z$ , in the Northern Galactic Hemisphere, so we are presumably situated appreciably off-centre. A schematic diagram of a possible arrangement of clusters is shown in Fig. 1. We emphasize that this diagram is purely illustrative, and may require modification when further red-shifts are determined. Two features are, however, worth noting. First, it provides a natural explanation of the fact that quasars with  $z \sim 3$  have not yet been observed, although on grounds of radio flux density and apparent optical magnitude such red-shifts would be expected. (This point has been stressed, in conversation, by Prof. E. M. Burbidge.) Second, we can derive a relation between the angular diameter  $\theta$  of a roughly spherical cluster and its minimum and maximum red-shifts  $z_1$  and  $z_2$ . In a low density universe with  $x \sim 3$ , the self-gravitation of clusters would be unimportant. A straightforward calculation then gives

$$\tan^2 \theta / 2 = \frac{4(z_2 - z_1)^2 (1 + z_1 + z_2 + z_1 z_2)}{(z_1 + z_2 + z_1 z_2)^2 (2 + z_1 + z_2)^2 - (2 + z_1 + z_2 + z_1 z_2)^2 (z_2 - z_1)^2}$$

The existing data suggest that  $z_1 \sim 1$ ,  $2 < z_2 < 3$ , for which  $24^\circ < \theta < 33^\circ$  (a result which depends insensitively on the cosmological model). Thus, the computed angular diameter is in reasonable agreement with the observed angular diameters. Our own cluster, as drawn, would be comparable with the other two observed clusters.

Fig. 1. Schematic diagram of a possible arrangement of (spherical) quasar clusters. The diagram shows a section of the world picture as seen by an observer O on our Galaxy. Circles of constant red-shift  $z$  are drawn for  $z = 0.5, 1$  and  $3$ . The section is chosen to pass through the North Galactic Pole and galactic longitude  $l \sim 110^\circ$ . It then passes through the centre of the two quasar clusters the existence of which is suggested by the distribution of quasars with large red-shift (ref. 1). These two clusters, and the cluster within which we may be situated, are heavily shaded. The position of the other clusters (lightly shaded) is purely conjectural, but the diagram shows a possible distribution, assuming that they have roughly equal masses and occupy about one-third of space. The directions within which quasars have not been observed, either because of galactic absorption or because of the low declination, are indicated by the shading outside the outer circle.

We now consider whether the large scale fluctuations we postulate could arise in a point source model universe. Little progress has been made in understanding the origin of the larger amplitude smaller scale fluctuations represented by clusters of galaxies. The mechanism which does produce galaxy clusters might, however, also produce our larger scale (but smaller amplitude) fluctuations, because in the early stages of the universe the background radiation is dynamically dominant and is likely<sup>30,31</sup> to smooth out density fluctuations contained within an observer's field of view<sup>32</sup> at that time (although larger fluctuations might persist). When the radiation ceases to dominate, instabilities on a scale smaller than the radius of the observable universe presumably grow, some of them developing into galaxy clusters. The largest possible such scale depends on  $T$  and  $\rho$ . For  $T \sim 3^\circ \text{K}$  and  $\rho \sim 5 \times 10^{-31} \text{g/c.c.}$  this scale would now be about 1,000 Mpc, in reasonable agreement with the apparent scale of the observed clustering. A theoretical determination of  $\alpha$  would require a detailed theory of the instabilities.

Finally, we consider some testable consequences of our model. It seems possible that one or two other clusters in the range  $1 \leq z \leq 3$  might be observable if a determined search were made at low galactic latitudes. In particular the sources in the region  $l \sim 210^\circ$ ,  $b \sim 20^\circ$  (not shown in the diagram) may be at the edge of a cluster. The fact that one of the observed clusters lies almost in the direction of the North Galactic Pole would, in our model, be a coincidence. If  $\rho \sim 10^{-30} \text{g/c.c.}$ , however, the microwave background radiation may exhibit anisotropy of up to a few per cent, especially in the general direction of the North Galactic Pole. We suggest that such anisotropy be looked for—its absence would, on our model, place a stringent upper limit on  $\rho$ . Another question concerns the isotropy of the radio source counts. Since there is a large dispersion in the intrinsic power of radio galaxies and quasars, radio source catalogues include, at the same flux density, intrinsically faint sources well within our own cluster, and very powerful sources in remote clusters. The large scale clustering suggested here might thus be consistent with the observed isotropy of the source counts<sup>3</sup>. Our proposed clustering would be most apparent if one were able to select objects from a small number of clusters—that is, in terms of their red-shift rather than their radio flux density—and this is precisely what Strittmatter, Faulkner and Walmesley<sup>1</sup> have done. A conclusive test of their proposal clearly requires more red-shift determinations. These should also show whether the quasars are indeed clustered in the manner suggested here.

We are grateful to Prof. C. W. Misner for helpful discussions, and to Dr. J. Faulkner and Mr. P. Strittmatter for informing us of their results before publication.

## Anisotropic Distribution of Quasars with Large Red-shift

Strittmatter, Faulkner and Walmesley<sup>1</sup> have suggested that there is an anisotropy in the distribution of quasars with large red-shift over the sky, pointing out that most of those discovered to date fall in two regions near the galactic poles. In this communication we present evidence that this anisotropy may be merely an effect of observational selection.

We confine our attention to sources identified from the revised 3C catalogue. Such identified sources might be expected to form a fairly homogeneous sample, and the identifications are about 80 per cent complete<sup>2</sup>.

In Fig. 1 we plot the visual magnitude of quasars identified from the 3C catalogue against their flux density at 1,400 Mc/s. Of the ten quasars in 3C known to have red-shifts greater than 1.38, seven are optically fainter than 18 magnitudes and have flux densities<sup>3</sup> at 1,400 Mc/s fainter than 3 f.u. ( $10^{-26} \text{Wm}^{-2} (\text{c/s})^{-1}$ ): this suggests that red-shift is correlated either with distance, as the cosmological theories and the simple single explosion local model require, or inversely with optical and radio luminosities. Hoyle and Burbidge<sup>4</sup> have pointed out that there is no clear red-shift magnitude relation for quasars either optically or at 178 Mc/s. We do not dispute this, but claim that most quasars with large red-shift have faint apparent optical magnitudes and radio flux densities at

Fig. 1. Plot of  $V$  against  $\log S_{1400}$  for 3C quasars. ●,  $z \geq 1.38$ ; ○,  $z < 1.38$ ; ▲, no  $z$  available.

1,400 Mc/s. (At 178 Mc/s even this weaker relationship does not obtain, because most of the sources which have the highest flux densities at 1,400 Mc/s have radio spectra which either curve down at lower frequencies, or have smaller values of the spectral index  $\alpha$  (where  $S(\nu) \propto \nu^{-\alpha}$ ). This correlation between high flux density at 1,400 Mc/s

and flatter radio spectra may also account to some extent for the steeper number-count slope found by Veron<sup>2</sup> for quasars ( $-2.2$  as opposed to  $-1.85$  for all sources.)

In Fig. 1 we see more 3C quasars without large redshifts have flux densities less than 3 r.u. at 1,400 Mc/s than are optically fainter than 18 magnitudes. Thus it is

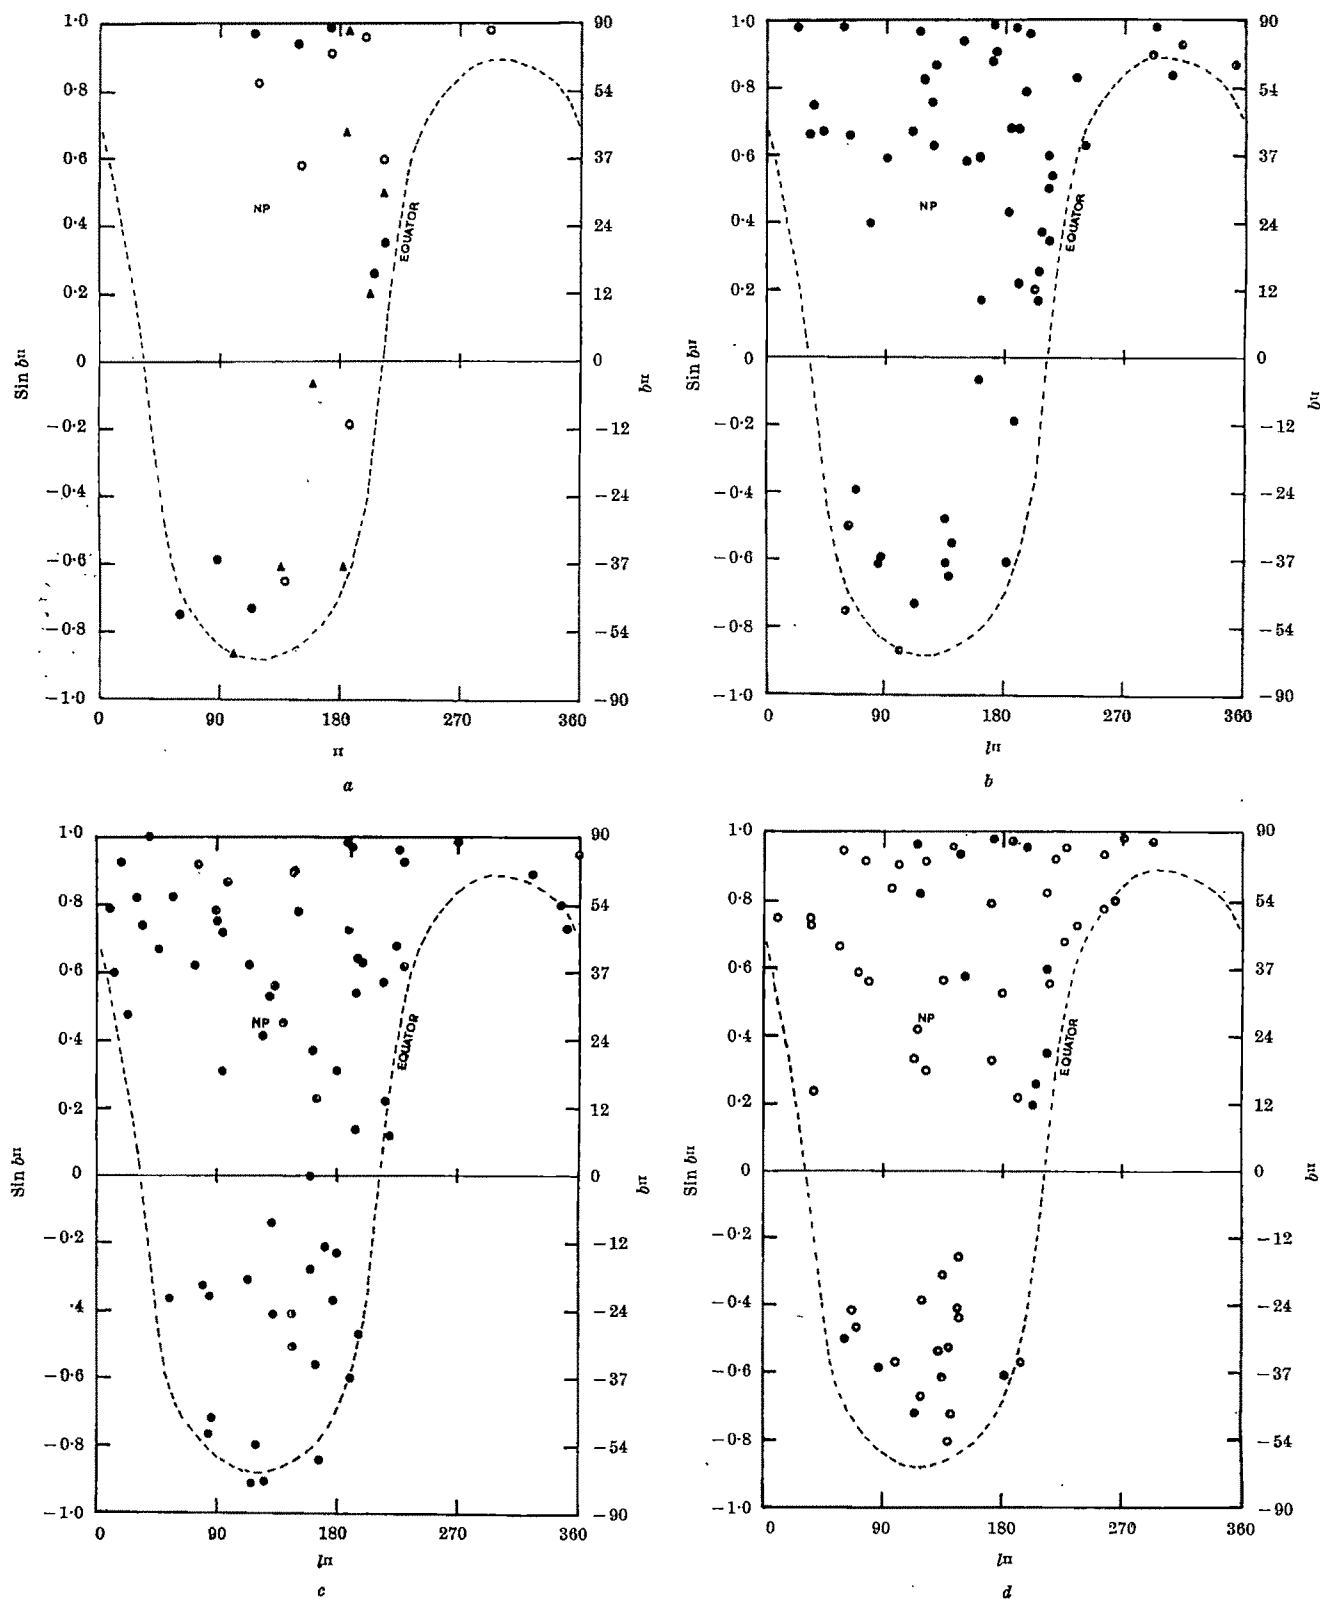

Fig. 2. Plot of  $\sin b_{II}$  against  $l_{II}$  for: a, 3C quasars with  $V \geq 18$  (symbols as in Fig. 1); b, 3C quasars all  $V$ ; c, 3C galaxies with  $V \geq 18$ ; d, 3C quasars with  $V \geq 18$  (●) and 3C unidentified sources (○). (d includes only radio sources with  $\log S_{1400} < 25.5$ .)

clear that apparent optical faintness is a more characteristic property of 3C quasars with large red-shifts than apparent radio faintness at 1,400 Mc/s.

In Fig. 2a we plot  $\sin b_{II}$  against  $l_{II}$ , where  $b_{II}$  and  $l_{II}$  are the galactic co-ordinates, for all 3C quasars which are visually fainter than 18 magnitudes. This is an equal area projection, but the galactic poles correspond to whole top and bottom margins of the diagram. The celestial equator is marked as a dotted line and the north celestial pole is marked "NP". No 3C sources lie far below this dotted line. As a result of galactic obscuration, few identifications can be made near the galactic plane ( $b_{II}=0$ ).

The distribution of points in Fig. 2a is markedly anisotropic: there is none in the region  $b_{II} > 0$ ;  $300 < l_{II}$  and  $l_{II} < 100$ . The eight quasars with large red-shift ( $\geq 1.38$ ) do not appear, however, to be distributed more anisotropically than the other sixteen quasars, eight of which have measured red-shifts less than 1.1. To see that the quasars identified in 3C are, as a whole, not especially anisotropically distributed Figs. 2b and 2c should be compared. Fig. 2b contains all quasars identified in 3C so far, while Fig. 2c contains all those radio galaxies listed by Wyndham<sup>4</sup> as being fainter than 18 magnitudes. We think that the anisotropy shown by those quasars in Fig. 2a with smaller red-shift may be an effect of selection. If this is the case, the anisotropy noticed by Strittmatter, Faulkner and Walmesley may have the same cause.

Our contention is thus that the primary anisotropy is in the distribution of quasars with  $V \geq 18$  rather than of those with large red-shifts (Strittmatter, Faulkner and Walmesley remark "observers in their quest for larger red-shifts may tend to investigate only fainter objects"). It is natural that any observational bias will be more severe for the fainter objects. Although Fig. 2c shows that there is no similar anisotropy for radio-galaxies with  $V \geq 18$ , galaxies may be identified with radio-sources from the *Palomar Sky Survey* alone, whereas quasars require three colour photometry to be performed. The region in which there are no optically faint quasars corresponds to the northern summer sky (right ascension 13 h 40 min to 22 h 40 min). Possible causes of observational selection may be: (i) shorter nights in the summer; (ii) the absence of the main quasar observers from California during the conference season; or (iii) difficulty in obtaining accurate radio positions through the galactic foreground radiation in the vicinity of the north polar spur.

In Fig. 2d we have superimposed the distribution of 3C quasars which are optically and radio faint on that of those 3C sources which are radio faint and not in regions of high absorption which are still unidentified ( $E$ ,  $E?$ ,  $?$ , in Veron's<sup>2</sup> notation). This distribution displays far less anisotropy than Fig. 2a, so that if some of the unidentified sources in the summer sky are quasars with large red-shift, then isotropy could be maintained. We await any further information on these unidentified sources with considerable interest.

## PLANETARY SCIENCE

### Enhanced Interplanetary Scintillations associated with Solar Flares

DURING the past year, a survey of radio sources at 195, 430, and 611 Mc/s has been undertaken at the Arecibo Ionospheric Observatory to determine the sources which scintillate as a result of irregularities in the interplanetary medium. The degree of the intensity scintillations observed on the Earth depends on the integrated fluctuations in the electron density along the line of sight in the interplanetary medium and on the scale size of these fluctuations<sup>1</sup>. Thus, by monitoring those sources which scintillate, some of the gross features of the interplanetary medium can be deduced. In particular, it should be possible to plot the passage of shock waves and the ejection of turbulent plasma associated with large solar flares, as the disturbance moves out from the Sun into the interplanetary region.

At the end of March 1966, a number of class II and class III flares appeared in two plage regions, *KD 07* and *KE 23*, situated near the west and east limbs, respectively, of the solar disk at latitude 20° N. Although we were unable to plot the passage of the associated disturbances, we were able to detect their presence on two occasions, through an anomalous increase in the value of the scintillation index,  $m$ , defined by

$$m^2 = \frac{\langle \Delta I^2 \rangle \text{ on source} - \langle \Delta I^2 \rangle \text{ off source}}{\langle I \rangle^2}$$

$\langle \Delta I^2 \rangle$  and  $\langle I \rangle$  are the variance of the intensity fluctuations and the mean intensity of the source. On March 27 the scintillation index was four times larger than expected for quiescent solar conditions for the sources 3C 454 and 3C 454.3, and on March 31 eight times larger for *OTA 21*.

The scintillation indices and the elongations for 3C 454 and 3C 454.3 are given in Table 1 for five days between March 6 and April 15. The data for *OTA 21* are presented in Fig. 1 as a plot of the scintillation index against elongation for the 4 week period beginning on March 26. The solid lines represent the best fit to the experimental points and display the observed dependence of the scintillation index on the source elongation for conditions of quiescent solar wind. For the range considered in this report, the dependence of the scintillation index on elongation is similar for most sources. Thus the expected quiescent behaviour for 3C 454 and 454.3 on March 27 can be deduced from the graph of *OTA 21* using the scintillation indices listed in Table 1 for the other 4 days of observation. This results in an average increase due to the presence of the disturbance of a factor 4.

Table 1

Source	Frequency (Mc/s)	6th	March 13th	27th	3rd April	15th
3C 454						
Scintillation index	195	0.11	—	0.78	—	0.20
	430	0.10	< 0.10	0.25	—	< 0.10
Elongation		25°	24°	28°		40°
3C 454.3						
Scintillation index	195	—	—	0.62	< 0.10	0.18
	430	—	—	0.35	< 0.10	< 0.10
Elongation				26°	31°	39°

The observed increase in the scintillation index reflects an increase in the root mean square fluctuations in the electron density  $\Delta n$ , produced by the disturbance. For *OTA 21* at 430 Mc/s, the scintillation index is less than 1, and the observer-disturbance distance can be taken to be about the same as the Fresnel range ( $\sim 1$  AU). Then  $\Delta n$ , and the half width of the scintillation frequency spectrum,  $b$ , as given by Salpeter<sup>1</sup> and Cohen<sup>2</sup> are

$$m_i \doteq \sqrt{(2) (2\pi)^{1/4} \lambda r_e (a_i L_i)^{1/2} \Delta n_i} \quad (1)$$

$$b_i \doteq 2.4 \frac{2u_i}{\pi a_i} \quad (2)$$

In these expressions  $a_i$  is the scale size of the fluctuations in the electron density,  $L_i$  is the line of sight screen thickness,  $u_i$  the mass velocity of the medium perpendicular to the line of sight, and  $r_e$  the classical radius of the electron  $= 2.83 \times 10^{-13}$  cm. The subscript  $i$  has the value 1 for the parameters associated with the disturbance on March 31 and the value 2 for those expected on the same day for quiescent solar conditions. Taking the ratio of the scintillation indices for these two conditions produces

$$\frac{\Delta n_1}{\Delta n_2} = \frac{m_1}{m_2} \cdot \frac{(a_2 L_2)^{1/2}}{(a_1 L_1)^{1/2}} = 8 \frac{(a_2 L_2)^{1/2}}{(a_1 L_1)^{1/2}}$$

where the numerical value 8 for the ratio  $(m_1/m_2)$  has been obtained for CTA 21 from Fig. 1.

As the scale size and the thickness of the disturbance are not known, it is necessary to appeal to the work of other authors and to make a number of assumptions regarding these parameters in order to obtain an estimate for the increase in the fluctuations in the electron density.

We have experimentally observed the increase in the width of the scintillation frequency spectrum ( $b_1/b_2$ ) to be a factor of 2. Wolfe *et al.*<sup>3</sup> and Neugebauer and Snyder<sup>4</sup> have observed an increase of 2 in the streaming velocity of the interplanetary medium after substantial solar activity, so  $u_i$  can be taken to be approximately equal to  $2u_2$ , indicating that  $(a_2/a_1)^{1/2}$  can be taken to be of the order of 1. The density fluctuations during quiescent solar conditions are observed to obey a  $1/r^2$  law<sup>2</sup>. For this dependence Cohen *et al.*<sup>2</sup> have shown that the main contribution to the scintillation phenomena is produced by an effective screen thickness in A.U. of  $L = (2/\sqrt{3}) \sin$  (elongation). If it is assumed that the density fluctuations associated with the disturbance also have a  $1/r^2$  dependence, the ratio  $(L_2/L_1)^{1/2}$  can be set greater than or equal to 1, depending on whether the disturbance along the line of sight is smaller or larger than the effective screen given here for the elongation occurring on March 31. This leads to a minimum value of eight for the increase in the fluctuations of electron density associated with the disturbance.

Because the intensity scintillations are dependent only on the fluctuations in the electron density, the actual increase in the overall mean density associated with the disturbance cannot be determined.

Fig. 1. The scintillation index for the source CTA 21 at frequencies of 195 (○), 430 (□) and 611 (×) Mc/s, plotted as a function of time with the source elongation included on the abscissa. The graph shows a marked increase in the value of the scintillation index on March 31 after type II flares on the solar disk.

Fig. 2. The relative position of the sources observed on March 27 (●) and 31 (+) with respect to the Sun and the ecliptic in the plane of the sky. The latitude and the relative longitude with respect to the Sun are in ecliptic co-ordinates. The circles represent those sources which exhibited a large increase in their scintillation index.

In Fig. 2, the relative positions of the sources are plotted with respect to the Sun in geocentric ecliptic co-ordinates. 3C 454 and 3C 454.3 with elongations of 28° and 26°, respectively, are positioned to the north-west of the Sun while CTA 21 is to the east near the ecliptic at an elongation of 42°. On the same diagram seven other sources observed during this period have been plotted. They are known to scintillate but did not display a large increase.

It is interesting to note from Fig. 2 that (1) the activity on March 27 was observed in a region 40° N. of the projection of the flare normal on the plane perpendicular to the line of sight, and (2) that on March 31 either the main part of the disturbance had passed the position of 3C 49 or else the angular direction of the disturbance with respect to the ecliptic was less than 15° N. For the latter case, as with the activity of March 27, the data suggest that the disturbance can propagate at an oblique angle to the flare normal. A definite velocity for the disturbance cannot be deduced because the activity of March 27 was preceded by some ten well separated class II or III flares, while the activity of March 31 was preceded by five well separated class II flares after March 27, when the KE 23 group was first observed on the east limb. Nevertheless, assuming the disturbance travels faster than the solar wind, the data for March 31 are consistent with the velocities of 500–600 km/s found by Wolfe *et al.*

The large increases in the interplanetary scintillations observed after substantial solar activity suggest that the careful monitoring of a grid of sources known to scintillate will be a powerful method for the determination of the influence of such activity on the interplanetary medium and the structure and propagation characteristics of the resultant shock waves.

We thank I. Axford, M. Cohen, E. Gundermann and C. Hazard for interesting discussions.

The Arecibo Ionospheric Observatory is operated by Cornell University with the support of the Advanced Research Projects Agency under a research contract with the U.S. Air Force Office of Scientific Research.

## Interpretation of the Continuous Spectra of Comets

COMETARY dust, as well as being one of the basic features of comets, is of importance in several major problems of the solar system: it is most nearly representative of solid particles in the primordial solar nebula<sup>1</sup>; it is a contributor to zodiacal light<sup>2</sup>; and, although Harwit<sup>3</sup> has questioned its effectiveness, it plays some part in processes in interplanetary space<sup>4</sup>. Information concerning the nature of the dust can be obtained at present only by an analysis of scattered sunlight in the heads and tails of comets.

Mie scattering calculations for single particles and for cumulative scattering functions<sup>5</sup> were carried out on a computer at Goddard Space Flight Center<sup>6</sup>. These results were applied to measurements of the continuum in two ways.

Quantitative calculations were carried out for size distributions of the form

$$f(a) = Ca^a, a_1 \leq a \leq a_2 \quad (1)$$

where  $a_1$  and  $a_2$  are minimum and maximum radii and  $a$  took on integral values between  $-4$  and  $2$ . Five size ranges were used for each distribution:

- case (a)  $5 \times 10^{-7} \leq a \leq 1.5 \times 10^{-4}$  cm
- (b)  $5 \times 10^{-7} \leq a \leq 5 \times 10^{-6}$
- (c)  $1.5 \times 10^{-6} \leq a \leq 1.5 \times 10^{-4}$
- (d)  $5 \times 10^{-6} \leq a \leq 1.5 \times 10^{-4}$
- (e)  $5 \times 10^{-5} \leq a \leq 1.5 \times 10^{-4}$  cm

Both intensity and degree of polarization were computed and compared with observations of the comets 1957 III and 1957 V (ref. 7). They follow the same procedure as used previously<sup>8</sup>.

Cumulative scattering functions<sup>5</sup> are defined as

$$F_j(X) = \int_0^X i_j(x) dx \quad (2)$$

where  $X = 2\pi a_{\max}/\lambda$  and runs from 0.1 to 25 in steps of 0.1 and the subscript  $j$  represents either of the two polarization components. These functions were used to obtain qualitative characteristics of scattering by dielectric and iron spheres. In this analysis there was no restriction on the shape of the particle distribution nor of the size range for  $X$  less than 25. Comparisons were made between these data and observations of comets 1957 III and 1957 V.

In each investigation it was found that the observed degree of polarization, about 20 per cent, was too low to be caused by a distribution of iron spheres as proposed by Liller<sup>9</sup>. The small variation of polarization with wavelength also supported this. We conclude that iron grains can make only a small contribution to the scattering in comets. The observations can be explained, however, by the presence of a cloud of dielectric particles.

Some preliminary calculations indicate that scattering from carbon grains will resemble scattering from iron. For scattering angles close to 90°, calculations for spheres agree rather closely with measurements on non-spheroidal particles<sup>5</sup>.

Infra-red measurements were made on the comet Ikeya-Seki<sup>10</sup> by Beklin and Westphal in four wavelength intervals: 1.5–1.8 $\mu$ , 2.0–2.4 $\mu$ , 3.0–3.8 $\mu$  and 8.4–13.5 $\mu$ . Infra-red emissivities were derived on the assumption that molecular emission could be neglected. The calculations were corrected for scattered sunlight. Spectra in the 2.2 $\mu$  region are quoted as showing less than 10 per cent line emission. A survey of predicted infra-red emissions in comets<sup>11</sup> shows that the 3.4 $\mu$  region should be rich in molecular emission, much more so than the 2.2 $\mu$  region. The 10 $\mu$  region was not examined nor were atomic lines in the infra-red. Without spectroscopic study, it is not safe to assume that the measurements of the 3.4 $\mu$  and 10 $\mu$  filters are not affected by atomic or molecular emis-

sions. It is well known that, to make intensity measurements of the continuum in the visible, great care is required in the choice of wavelength regions passed by the filters.

In seeking to match their deduced emissivities Beklin and Westphal<sup>10</sup> used the optical properties of bulk material and suggested that iron gave a satisfactory fit. Cometary grains cannot be larger than a few microns radius without requiring excessive mass<sup>12</sup>. A similar limiting radius is required for the grains to be carried along by the escaping molecules<sup>13</sup>. For sizes less than the limiting radius the emissivity depends on the ratio radius/wavelength as well as index of refraction. Thus, even for the emissivities derived by Beklin and Westphal, it is not valid to say that iron is satisfactory without determining the emissivities of small grains.

Weinberg<sup>14</sup> has obtained extensive measurements of the intensity and polarization of the continuum of the comet Ikeya-Seki at 8 wavelengths throughout the visible spectrum. The analysis of this material will be of great value for the interpretation of the continuum of comets. The difficulty of making a unique determination of the nature of a cloud of scattering particles from optical observations is well known. Measurements of intensity and polarization over a wide wavelength interval and over as large a range of scattering angles as possible are necessary for interpreting the continuum of comets.

## Secular Movement of the Zone of Auroral Blackout

THE magnetic dip pole in 1922 and 1942 was close to the position 71° N. 97° W. whereas in 1955 and 1965 it was near 76° N. 101° W.<sup>1</sup>. A test has been made to find whether this movement was accompanied by changes in the rate of occurrence of radio blackout near Inverness (57.5° N., 4° W.) using the  $f_{min}$  tables from the vertical incidence data taken in this area between 1942 and 1963. The ionograms are reasonably comparable for the period. Data for months on which the number of blackout entries ( $B$ ) were abnormally large because of low critical frequencies at night were rejected. Independent studies were made for epochs near solar minimum, 1942–43 and 1962–63, and near solar maximum, 1946–47 and 1957–58, and significant differences

in the numbers of days with blackout were found for both sets of data.

At Inverness blackout mostly occurs on days with at least one value of  $Kp \geq 6$  and there were appreciably fewer such days in 1962-63 than in 1942-43. Correcting to equal effective levels of magnetic activity, the ratio of the number of days per month with blackout for the periods before 1950 to those after 1950 was 1.7 in both cases. This strongly suggests a real change in the position of the blackout zone.

The network of ionospheric stations in Northern Europe is not sufficiently dense to allow more than a rough estimate of the long term change in geomagnetic latitude of the lines which represent a constant number of days of blackout. The best estimate from these data is between  $3^\circ$  and  $6^\circ$ , but there is a large possible error caused by systematic differences in the relative sensitivity of the stations and errors in analysis. It is therefore not known whether the rate of change of blackout with latitude is the same as that of zenith aurora or is slower, as suggested by the absorption data.

Using the number of days with zenith aurora between  $58^\circ$  and  $63^\circ$  magnetic latitude over the U.K. (Paton, J., private communication) and assuming that blackout and zenith aurora have the same rates of change with latitude, the most probable shift in the lines of constant blackout activity between the epochs 1942-47 and 1957-63 is about  $2^\circ$ . There therefore appears to have been a real change in the position of the blackout zone.

## CHEMISTRY

### Separation and Analysis of some *cis,trans* Isomeric Olefines on Activated Alumina

PREVIOUS investigations have shown that gas-solid chromatography (GSC) on activated alumina is useful in separating paraffins and olefines from  $C_1$ - $C_8$  (refs. 1-3). The physicochemical characteristics of the solute and its affinity for the adsorbent determine the efficiency and limitations of alumina GSC. The choice of carrier gas for adsorption chromatography has a marked effect on retention times and column efficiencies<sup>4</sup>. Solute characteristics that influence the degree of separation attained include differences in boiling points, molecular branching, and the presence of double and triple bonds.

Jacobs<sup>5</sup> has separated *cis,trans* butenes from automotive exhaust gases by temperature programming from  $-55^\circ\text{C}$  to  $140^\circ\text{C}$ , using a 150 ft. capillary gas-liquid chromatographic column in conjunction with a flame ionization detector. Chromatographic curves show that isomeric 2-butenes were well separated and retention times are tabulated for  $C_5$  and  $C_6$  isomers. No separations of the isomeric 3-heptenes were obtained, however, and data for higher molecular *cis,trans* isomers were not presented. Isomeric 2-butenes have a comparatively large difference in boiling points and have been separated on propylene carbonate-modified alumina<sup>6</sup>. Such analytical columns, however, are of limited value for higher homologues because of low thermal stability of the liquid phase. Although distinguishing between low molecular weight *cis* and *trans* hydrocarbon isomers by infra-red spectra is difficult<sup>7</sup>, the technique has been used<sup>8</sup>. The method requires skilled application, because Sadler's infra-red index<sup>9</sup> shows the spectra for both *cis* and *trans* 2-butene to be virtually identical. The spectra for 2-pentene pub-

Table 1. PHYSICAL CONSTANTS OF SOME *cis,trans* HYDROCARBONS<sup>10</sup>

Isomer	Boiling point (°C at 760 mm)	Heat of vaporization (Kcal/mole) at bp	Difference
<i>cis</i> -2-Butene	3.72	5.57	
<i>trans</i> -2-Butene	0.88	5.43	0.14
<i>cis</i> -2-Pentene	36.94	6.24	
<i>trans</i> -2-Pentene	36.35	6.22	0.02
<i>cis</i> -2-Hexene	68.84	6.91	
<i>trans</i> -2-Hexene	67.87	6.89	0.02
<i>cis</i> -3-Heptene	95.75	7.53	
<i>trans</i> -3-Heptene	95.67	7.52	0.01
<i>cis</i> -2-Octene	125.64	8.05	
<i>trans</i> -2-Octene	125.0	8.03	0.02

lished in this index do not indicate which isomer was used for establishing the absorption curves. The need for a rapid method to separate and quantitate each isomeric component is apparent.

Table 1 shows a series of *cis,trans* isomeric olefines separated by GSC on activated alumina. In all isomeric pairs the *trans* component exhibited the lower boiling point. Differences in boiling points between individual isomers, however, do not account for the observed degree of separation between the components. For example, the 2-pentenenes, of which the boiling points are nearly identical, are about as well separated as the 2-butenes that boil about  $3^\circ\text{C}$  apart.

Heats of vaporization at the boiling points are lower for the *trans* isomer<sup>10</sup>. Heats of adsorption reportedly have the same magnitude as the latent heats of vaporization<sup>11</sup>, and although the differences shown in Table 1 are small they are consistently higher for the *cis* isomer. Enhanced adsorption of *cis* relative to the *trans* isomer was pointed out by Scott<sup>12</sup> to be a general phenomenon for solid surfaces. He indicates that separation on gas-solid columns can be achieved with only a fifth or a tenth of the plates needed in gas-liquid columns. Our separations of *cis,trans* isomers on short columns of activated alumina indicate a high degree of adsorption. Because GSC separations are based on adsorption rather than partition between gas and liquid phases, the electrokinetic interactions between solute and adsorbent contribute the physical forces necessary to resolve components.

Fig. 1. Photographs of molecular models of *cis* and *trans*-2-pentene. Upper, a top view; lower, a side view.

Fig. 2. Separation of some *cis,trans* isomeric hydrocarbons on activated alumina: A, 2-butene; B, 2-pentene; C, 2-hexene; D, 3-heptene; and E, 2-octene. The instrument used was an F and M 1609 flame ionization detector with column 3 ft.  $\times$  1/16 in., 60/80 mesh activated alumina; chart speed 30 in./h, carrier gas, nitrogen 40 c.c./min; and column temperatures isothermal: A at 75°C; B at 100°C; C at 115°C; D at 150°C; and E at 175°C.

From a photograph of a molecular model of *cis* and *trans* 2-pentene (bottom of Fig. 1), it is evident that electron clouds surrounding a *cis* double bond can lie closer to the alumina surface than can those of the *trans*. The *cis* isomer, more strongly bound than the *trans*, desorbs less readily. This retentive mechanism accounts for their observed elution order<sup>12</sup>. Giddings<sup>13</sup> states that a small bore column should give optimum results for GSC separations.

This investigation shows it to be useful for even the difficult task of separating *cis,trans* isomers.

Table 2. ANALYSIS OF 2-BUTENE ISOMERS

Known composition (per cent)		Found by gas solid chromatography (per cent)	
<i>trans</i>	<i>cis</i>	<i>trans</i>	<i>cis</i>
9.7	90.3	10.5	89.5
35.1	64.9	37.0	63.0
53.7	46.3	53.7	46.3
70.0	30.0	67.4	32.6
100.0	—	100.0	—
—	100.0	—	100.0

Fig. 2 shows GSC separations of a homologous series of  $C_4$ - $C_8$ -*cis,trans* isomeric olefines. Although  $\frac{1}{8}$ -in. diameter columns gave adequate separation of the isomeric 2-butenes and 2-pentenenes, they were unsatisfactory for resolution of the isomeric 2-hexenes, 3-heptenes and 2-octenes. A 3 ft. standard column of outer diameter 1/16 in. gave good separation of all components under the conditions indicated. Even though the higher  $C_{6,7,8}$  members were not so completely resolved as the lower  $C_4$  and  $C_5$  isomers, results indicate that the separations are useful for qualitative analysis of hydrocarbon mixtures containing such geometrical isomers. Resolution achieved for the butenes and pentenes permits integration to quantitate their proportions, and the results for most samples agreed closely with the suppliers' analyses. One sample, however, erroneously labelled mixed 2-butene isomers, was analysed and found to be 100 per cent *trans*. Variation in amounts of geometrical isomers in a commercial 2-butene is reported<sup>14</sup> within the limits of 50-67 molecular per cent *cis* content based on infra-red and freezing point. Our analysis of this sample indicated a *cis* content of 72 per cent. Analyses of mixtures of butenes containing 100 per cent *cis* to 100 per cent *trans* 2-butenes have shown reasonable agreement with the known isomer contents (Table 2). The 2-butene mixtures analysed and reported in Table 2 were prepared by mixing known volumes of pure *cis* and *trans* 2-butenes in a manometric apparatus equipped with mercury levelling bulbs. The accuracy of this method is limited to how accurately one can read the burette used in the apparatus. Complete resolution of the two isomers was not obtained (Fig. 1) and errors in integration are inevitable.

Under proper chromatographic conditions of column length and diameter, sample size, column temperature, and choice of carrier gas, alumina GSC lends itself well to volatile hydrocarbon analysis. It can separate saturates and unsaturates, as well as iso- and cyclic hydrocarbons<sup>1</sup>.

### Role of $O^-$ in the Gas Phase Radiolysis of Alkane-Nitrous Oxide Mixtures

WHEN an alkane gas is irradiated in the presence of nitrous oxide, nitrogen is formed. This has been shown to result from the dissociative capture of electrons by nitrous oxide<sup>1</sup>

At constant dose rate the yield of nitrogen,  $G(N_2)$ , obeys the expression

$$\frac{1}{G(N_2)} = \frac{1}{G(N_2)_\infty} \left( 1 + \frac{A}{[N_2O]} \right)$$

expected for competition between electron capture and ion recombination.  $G(N_2)_\infty$  is a constant, for a given hydrocarbon, and represents the yield of nitrogen when all electrons are captured. The fact that  $G(N_2)_\infty$  is greater than the yield of electrons,  $G_e$ , calculated from the  $W$  value<sup>3</sup>, has been ascribed to the subsequent reaction of  $O^-$  with nitrous oxide<sup>1,2</sup>. Evidence has been found, in the mass spectrometer, for reactions (2) and (3) (ref. 4). The relative rates of these reactions are not, however, reported.

Fig. 1. The effects of carbon dioxide (●) and acetone (○) on  $G(N_2)$  from a propane (600 mm. mercury)-nitrous oxide (25 mm. mercury) mixture.

On the basis of the ethylene dosimeter\* ( $G(C_2H_4 \rightarrow H_2) = 1.31^3$ ),  $G(N_2)_\infty$  for the  $C_2$ ,  $C_3$  and  $C_4$  alkanes is found to be  $1.55 G_e$  (to be published). This can be explained by assuming a rate constant ratio,  $\frac{k_2}{k_3} = 1.22$ .

It has been found, in the mass spectrometer, that the predominant negative ion formed in oxygen containing carbon dioxide is  $CO_3^-$  (ref. 5). This has been attributed to the fast reaction

Carbon dioxide is not known to react with the radical or ionic species produced in alkane radiolysis. It was therefore thought that the addition of carbon dioxide to alkane-nitrous oxide mixtures might provide unambiguous evidence for reaction (2) by competing with nitrous oxide for  $O^-$  thereby decreasing  $G(N_2)_\infty$ . Carbon dioxide was, in fact, found to decrease  $G(N_2)_\infty$  even for  $[CO_2]/[N_2O]$  as low as 0.02 (Fig. 1). Higher concentrations of carbon dioxide further decreased  $G(N_2)_\infty$ , in the limit, to  $G_e$ . From other experiments the ratio  $k_4/k_2 + k_3$  has been determined to be 44 (to be published). The curve in Fig. 1 was computed using this ratio in the kinetic expression, for the dependence of  $G(N_2)_\infty$  on  $[CO_2]/[N_2O]$ , derived by a steady state treatment of reactions (2), (3) and (4). The agreement between this curve and experiment, together with the known reactivity of carbon dioxide towards  $O^-$  and the decrease of  $G(N_2)_\infty$  to  $G_e$ , is taken as conclusive evidence for the occurrence of reactions (2) and (3).

It has been found that the addition of small amounts of acetone to alkane-nitrous oxide systems increases  $G(N_2)_\infty$ , in the limit, to  $2G_e$  (Fig. 1). This can be explained by a competitive reaction of  $O^-$  with acetone (AO) to produce a species which later reacts with nitrous oxide quantitatively to form nitrogen.

The upper curve in Fig. 1 was computed from the expected variation of  $G(N_2)_\infty$ , in such a competition, using a value of  $k_5/k_2 + k_3 = 23.5$  obtained from other data (to be published).

\* Based on  $G(C_2H_4 \rightarrow H_2) = 1.31$ ,  $G(N_2O \rightarrow N_2)$  was found to be 10.0 in agreement with the latest reported value<sup>6</sup>

It is possible that the anomalously high yields of nitrogen (that is,  $> G_e$ ) observed with solutions of nitrous oxide in high pH water and liquid alkanes<sup>7-9</sup> also result from the subsequent reaction of  $O^-$  with nitrous oxide. The use of carbon dioxide as an  $O^-$  scavenger in the latter system should, therefore, prove of interest. Further investigations of the reactions of  $O^-$  with other additives are in progress.

### Measurement of the Rate Parameters for Reaction of $O(2^3P)$ with Carbon Disulphide and Olefins, by Flash Spectroscopy

THIS communication reports the measurement of the rate parameters for some reactions of  $O(2^3P)$  by a new application of flash spectroscopy, which could be adapted to a wide range of fast reactions. The intermediate, the reactions of which are under investigation, is directly produced by the photolytic flash; the method requires the selection of a substance which reacts with the intermediate to produce a molecule which has intense light absorption at a wavelength suitable for kinetic spectroscopy. The reaction rate is determined by observing the rate of formation of this product, and the relative rates of competing reactions with added compounds can be measured by observing the diminishing yield of the "marker". The rate of a reaction, in which neither reactants nor products exhibit convenient absorption spectra, can then be determined by the spectroscopic technique. In this investigation carbon monosulphide was produced by reaction of atomic oxygen with carbon disulphide and served as an ideal spectroscopic marker, because it possesses an intense band system at about 2600 Å. and because its lifetime is very long compared with the time in which measurements need to be made.

Mixtures of nitrogen dioxide and carbon disulphide, in an excess of argon, were flashed to produce  $O(2^3P)$ . By filtering the light through 'Pyrex', the production of excited oxygen atoms and the direct photolysis of carbon disulphide were avoided. The addition of argon prevented any significant temperature change and ensured rapid quenching of electronically excited nitrogen dioxide produced by absorption at long wavelengths<sup>1</sup>. The subsequent fate of  $O(2^3P)$  was monitored by spectroscopic observation of carbon monosulphide formed in the reaction

The rate constant of (1) was determined with  $[NO_2]/[CS_2]$  ratios of about 1:10; with a flash energy of 2,500 J; only a very small fraction of the atomic oxygen reacted with residual nitrogen dioxide. The absolute concentrations were adjusted to produce carbon monosulphide in a pseudo first-order reaction with a half-life of about 100 μsec. The finite duration of the photolytic flash was considered in the analysis of the results which gave

$$k_1 = 2.5 (\pm 0.3) \times 10^9 \text{ l. mole}^{-1} \text{ sec}^{-1} \text{ at } 305^\circ \text{ K}$$

$$\text{and } \log k_1 = 9.8 (\pm 0.2) - \frac{600 (\pm 300) \text{ cal/mole}}{2.3 RT}$$

From a study of the reduction of the yield of carbon monosulphide on addition of iso-butene or but-1-ene to mixtures of nitrogen dioxide and carbon disulphide the rate constants for addition of oxygen atoms to the olefines were obtained.

The high pressure of argon (100 mm) prevented fragmentation of the "hot" epoxide which Cvetanović has observed at low pressures in his detailed study of these reactions<sup>2</sup>. Concentrations of carbon monosulphide were measured at 900  $\mu\text{sec}$  and from plots of  $[\text{CS}]^{-1}$  v  $[\text{butene}]$   $[\text{CS}_2]^{-1}$ , the ratios  $k_2/k_1$  were determined. The rates of the reactions

and

have also been measured with this technique and are required for the accurate evaluation of  $k_2$  (ref. 3). The rate constant derived for reaction (3) is in excellent agreement with that recently reported by Klein and Herron<sup>4</sup>. For iso-butene,  $k_2/k_1 = 3.1$  at 298° K and 2.5 at 410° K, and for but-1-ene,  $k_2/k_1 = 0.78$  at 298° K and 0.83 at 410° K.

These results are compared with previous measurements in Table 1. Cvetanović has measured the rate constants relative to  $k_3$  and the conversion to absolute values has been made with  $k_3 = 3.28 (\pm 0.33) \times 10^6$  l. mole<sup>-1</sup> sec<sup>-1</sup> (ref. 4). His activation energies are relative to that for O + tetramethyl ethylene which is set equal to zero.

Table 1. RATE CONSTANTS (L. MOLE<sup>-1</sup> SEC<sup>-1</sup>  $\times 10^6$ ) AND ACTIVATION ENERGIES (KCAL/MOLE)

	This work		Cvetanović <sup>2</sup>		Elias <sup>5</sup>		Avramenko <sup>6</sup>	
	$k_{298}$	$E_a$	$k_{298}$	$E_a$	$k_{298}$	$E_a$	$k_{298}$	$E_a$
Iso-butene	7.6 ( $\pm 1.2$ )	0.1 ( $\pm 0.4$ )	7.5	0.47	10	0.4	0.03	2.5
But-1-ene	1.9 ( $\pm 0.3$ )	0.8 ( $\pm 0.4$ )	1.7	1.40	3.1	0.85		

The following comparisons are noted: (a) the first three sets of rate constants are in moderately good agreement but differ very significantly from those of Avramenko and co-workers; and (b) the absolute rate constants found in this work at 298° K are in excellent agreement with those of Cvetanović.

The measurements of Elias depend on consumption of atomic oxygen in a flow-system and removal of atoms in secondary reactions could result in slightly high values for  $k_2$ .

## THE SOLID STATE

### Arrangement of Rotating Molecules in the High-temperature Form of Normal Paraffins

NORMAL paraffins undergo a phase transition near the melting point into a crystal form which has been described as hexagonal. This form was first found by Müller<sup>1</sup>, who obtained hexagonal dimensions from X-ray powder data and therefore concluded that the molecules rotate in the lattice. Later, Bernal<sup>2</sup> reported a hexagonal cell for dodecanol in which the molecules lay along triad axes. Crystal forms with the chains arranged according to the same type of chains have then been found in other long-chain compounds, for example, simple esters and glycerides, and they have been termed  $\alpha$ -forms. The name  $\alpha$  will also be used for the high temperature crystal form of  $n$ -paraffins here, since it is inadequate to term it hexagonal as will be shown below. The nature of the molecular

motion in this crystal form of normal paraffins has been studied extensively, and the results indicate that the molecules are undergoing some kind of concordant rotation<sup>3-5</sup>.

The present author has examined  $\alpha$ -forms of mono- and tri-glycerides which occur in fat crystallization<sup>6</sup>. It was then realized that a detailed knowledge of the molecular packing in the simplest  $\alpha$ -form, that of paraffins, is of fundamental importance for the understanding of the behaviour of general  $\alpha$ -forms. An X-ray single-crystal investigation of the  $\alpha$ -form of a normal paraffin will be reported here.

$n$ -Nonadecane ( $\text{C}_{19}\text{H}_{40}$ ) was chosen because it exhibits an  $\alpha$ -form over a relatively wide temperature range near room temperature (21.9°–32.0° C). All the experiments were performed in a room where the temperature was kept constant at 25° C. Crystallization from solvents was tried in order to obtain the best conditions for crystal growth, although it was not certain that an  $\alpha$ -form could be obtained in this way. The behaviour on crystallization was very remarkable. A transparent and flexible film of paraffin was formed over the solvent (chloroform). Because the film prevented evaporation it was necessary to cut out openings in order to grow films thick enough to handle. The whole film proved to be a single crystal of the  $\alpha$ -form. Small pieces of the soft material were cut out for X-ray work, and oscillation and Weissenberg photographs were taken using copper  $K\alpha$  radiation.

A unit cell which corresponded to orthohexagonal axes was chosen in conformation with the earlier hexagonal description. The dimensions are:

$$a = 8.30 \pm 0.08 \text{ \AA}, b = 4.79 \pm 0.05 \text{ \AA}, c = 52.8 \pm 0.5 \text{ \AA}$$

The recorded X-ray data were of poor quality, but the reflexions were resolved, so that the orthorhombic symmetry and the dimensions in the reciprocal lattice could be established. The unit cell contains four molecules arranged in two molecular layers with vertical hydrocarbon chains. These layers are parallel to the film which is formed when the solvent evaporates, and the chain packing within each layer can be described by a hexagonal sub-cell. The lattice is shown in Fig. 1, where it is evident that the symmetry is not hexagonal. This is simply an effect of the relative displacement of adjacent molecular layers. Fig. 1 also illustrates the general features of the packing. The structure is viewed along the chain direction, and the molecular axes in the two molecular layers of the unit cell are then represented by circles and dots respectively. Many crystals were examined and disorder effects were frequently observed. The disorder corresponds to the occurrence of irregularities in relative displacement of adjacent layers, and may be due to sliding of molecular layers along (001) planes when the crystals are cut. The distribution of the reflexion intensities is in general agree-

Fig. 1. Lattice of the  $\alpha$ -form of  $n$ -nonadecane. The lattice points denoted by circles are situated  $c/2$  above (or below) those denoted by dots.

ment with the theoretical predictions for rotating chains by Vainshtein<sup>7</sup>. Electron diffraction photographs of the 2-form have also been recorded which confirm the earlier proposal of rotating chains (a diffuse halo was observed which fits very well with the calculated Fourier transform of a rotating chain).

Further analysis of the X-ray single crystal data of  $\alpha$ -forms in other long-chain compounds and additional studies by electron diffraction are in progress.

This investigation was supported by the Swedish Natural Science Research Council and the U.S. Public Health Service.

## PHYSICS

### Two-dimensional Nucleation of Ice

THE customary theory for the nucleation of ice on a crystalline substrate is based on the probability that a spherical cap of ice will grow, by statistical fluctuations, to a size such that the volume free energy and the surface free energy counterbalance<sup>1,2</sup>. Although this model is mathematically tractable, its validity has been questioned<sup>3,4</sup> on the grounds that the macroscopic values of the physical properties of ice may not apply to aggregates of only a few molecules. No alternative theory has yet been proposed to describe the molecular process by which ice deposits on a substrate. It is the purpose of this communication to show that the first stage in the nucleation of ice on organic nucleators is the growth of monolayer patches of ice on the nucleator surface.

The existence of an ice monolayer at the interface between a nucleator and supercooled water is not easy to detect directly, but because the thermodynamic properties of the monolayer differ from those of bulk ice it is possible, by the application of high pressure, to reach conditions under which bulk ice is unstable, yet the monolayer of ice can be formed and its properties can be studied.

The properties of the monolayer of ice can be investigated by studying the effect of pressure on the nucleation of Ice I by organic nucleators. The apparatus, which has been described previously<sup>5</sup>, enables the freezing point of a small droplet of an aqueous suspension of the nucleator to be measured under pressure. Temperatures are accurate to  $\pm 0.25^\circ\text{C}$ , and pressures are accurate to  $\pm 20$  bars. Of a large number of organic nucleators which have been studied, phloroglucinol dihydrate is a typical representative, and in this communication its behaviour is quoted as an example.

Fig. 1 depicts the conditions under which ice nucleates on phloroglucinol dihydrate under pressure, the supercooling required at any particular pressure being the vertical distance between the lines *CYC* and *DDZ*. Nucleation is enhanced by pressure and the supercooling necessary to nucleate ice falls from  $-6.5^\circ$  at atmospheric pressure to virtually zero at 1,500 bars. These results apply to droplets frozen for the first time. If, however, the droplets are melted, then frozen again, the second nucleation takes place at a temperature which depends on the maximum temperature to which the droplet is subjected during the melted stage. Specifically, if after melting the temperature is kept below  $-1^\circ\text{C}$  (for up to 20 min), the second freezing requires no supercooling,

while if the temperature exceeds  $+1^\circ\text{C}$  the original supercooling is required. This so-called memory effect is well known in other systems<sup>6</sup>, but on no previous occasion has a memory for ice persisted above the melting point of bulk ice<sup>7-9</sup> except for a passing observation by Bridgman<sup>10</sup> with regard to one of the dense polymorphs of ice. Because memory is lost above  $0^\circ\pm 1^\circ\text{C}$  regardless of pressure (*AA*, Fig. 1) it is apparent that at 2,500 bars the memory is retained  $29^\circ$  above the bulk melting point of ice, whereas at atmospheric pressure no memory can be detected.

The phenomenon of memory can arise in two distinct ways—either in the form of an unmelted ice layer or in the form of a structure imprinted on the phloroglucinol dihydrate surface by previous contact with ice. In the latter case, loss of memory would be a process akin to diffusion and would take place over a relatively wide temperature range in the vicinity of the Tammann temperature<sup>11</sup> of the nucleator. On the contrary, the results show that memory is lost over a narrow range between  $-1^\circ\text{C}$  and  $+1^\circ\text{C}$ , not only for phloroglucinol dihydrate but for the compound  $\alpha$ -phenazine the Tammann temperature of which differs markedly from that of phloroglucinol. Further, it has been found that when deuterium oxide is substituted for water, the memory is lost between  $+2^\circ\text{C}$  and  $+4^\circ\text{C}$ —a clear indication that the ability to retain a memory is a property of the water phase. That only a single monolayer of ice remains unmelted in the region *AACC* can be deduced in the following way. Because the melting point of the ice layer is not detectably altered by pressure (*AA*, Fig. 1) the volume change on melting the layer must be very small (compare the Clausius-Clapyron equation,  $dT/dP = \Delta V/\Delta S$ ). This condition can only be met by a single monolayer of ice because the packing density of water molecules in a single [0001] layer of ice is very close to that of liquid water, whereas a second layer of ice would drastically reduce the average density of the two layers to a value midway between that of ice and that of water.

Fig. 1. The  $P$ - $T$  phase diagram of Ice I. Curve *CYC* (—) is the melting point of ice as a function of pressure; curve *DDZ* (---) is the best line through the data points (○) which represent the temperature of the "first freeze" of ice by phloroglucinol dihydrate under pressure. Line *AA* (—) is the melting point of an ice monolayer; line *BB* (—) is the temperature at which an ice monolayer becomes fully developed.

The foregoing experiments show that once ice has been formed on phloroglucinol dihydrate, a monolayer persists at temperatures up to 0° C. To show how the ice monolayer participates in the initial nucleation of a water droplet, a further hypothesis must be made, namely, that although the ice monolayer melts at 0° C it does not freeze at 0° C but develops gradually as the temperature is lowered below 0° C. This hypothesis has been proved by carrying out experiments of the type described by the sequence *VWXYZ* (Fig. 1). *VW* represents a drop of water containing phloroglucinol dihydrate being cooled at 2,500 bars from room temperature to a temperature  $T_w$  which is above the melting point of bulk ice. *WX* represents decompression to 500 bars, keeping the temperature always between *AA* and *CC*. *XYZ* represents cooling at 500 bars. During this last step, *XYZ*, bulk nucleation takes place. It is found that the supercooling, relative to the point *Y*, at which bulk nucleation takes place, depends on the temperature,  $T_w$ , at the point *W*. As  $T_w$  is lowered the necessary supercooling during step *XYZ* diminishes, reaching a value of zero when  $T_w$  is -15° C or below. Clearly, the monolayer has progressively developed during stage *VW* without the prior formation of bulk ice, and having once developed it persists during step *WX* and is therefore available to promote bulk nucleation during step *XYZ*. At -15° C the monolayer may be defined as "fully developed", that is, the monolayer is capable of nucleating bulk ice at zero supercooling. This definition does not imply that the organic surface is completely covered by an ice monolayer. By carrying out the step *VW* at various pressures between 1,500 bars and 3,500 bars it can be shown that the monolayer becomes fully developed at -15° C regardless of pressure. It is a reasonable extrapolation to deduce that at atmospheric pressure also the temperature at which the monolayer becomes fully developed is -15° C (*BB*, Fig. 1).

In general, it may therefore be stated that at all pressures the nucleation temperature of bulk ice is the temperature at which the monolayer becomes sufficiently well developed to act as a nucleator for bulk ice at the ambient bulk supercooling. Thus the influence of pressure on the temperature of nucleation of bulk ice (*DD*, Fig. 1) is explained as follows. At atmospheric pressure, bulk ice nucleates at -6.5° C because the monolayer, though poorly developed, is able to nucleate the bulk at a bulk supercooling of 6.5°. At 500 bars, bulk ice nucleates at -8° C, because, although the bulk supercooling of 4° is less than that at one bar, the monolayer is better developed at the lower temperature. At pressures exceeding 1,500 bars, zero supercooling is required because the monolayer is already fully developed by the time the temperature falls to the bulk melting point.

An important corollary to the present work is the demonstration that, in reality, the first stage in the nucleation of ice by an organic nucleator is the development on the nucleator surface of an ice monolayer—presumably in patches centred on the sites of lowest interfacial energy. Such a process which is equivalent to the nucleation of an intermediate phase is not considered by theories which treat the growth of the ice embryo as a dynamic equilibrium, dependent on statistical fluctuations.

## Difference between Prompt and Delayed Fluorescence Spectra

It is commonly assumed that the emission spectrum of the delayed fluorescence of an organic material is identical with that of the prompt fluorescence, because the two spectra arise from a radiative transition between the same two electronic levels, although the origin of the excitation differs. Recently a difference has been reported between the prompt and delayed fluorescence spectra of fluorescein in boric acid<sup>1,2</sup> and of tryptaflavin in polymethyl methacrylate<sup>3</sup>. Three possible causes of the phenomenon have been suggested<sup>2</sup>: (1) the possible existence of two metastable (triplet) levels,  $T_1$  and  $T_2$ , in some molecules; (2) intermolecular migration of the triplet excitation energy; and (3) a possible difference in the transition probability distribution for prompt and delayed fluorescence.

The effect has now been observed in proflavin in polymethyl methacrylate solid solution. Proflavin (BDH Laboratory Chemicals) was purified, recrystallized, dissolved in ethanol and mixed in suitable proportions with methyl methacrylate. The solutions were acidified by the addition of a small amount of hydrochloric acid, so that the final solutions consisted of methyl methacrylate + 5 per cent ethanol + 0.1 per cent hydrochloric acid + proflavin. The solutions were placed in glass tubes, of 3 mm internal diameter, and the residual space was evacuated (to eliminate oxygen which quenches the proflavin phosphorescence), filled with nitrogen, and flame-sealed. The solutions were then polymerized thermally in the dark.

A xenon lamp was used for luminescence excitation at a wavelength of 365 nm, and the emission spectra were measured with an Aminco-Keirs spectrophosphorimeter. The luminescence was observed normally to the direction of incidence of the exciting light. No correction was applied for resorption and secondary luminescence, because the spectra of the prompt and delayed fluorescence were observed under the same conditions, and should therefore be affected in the same way by any such effects.

Fig. 1 shows (1) the prompt and (2) the delayed fluorescence spectra at room temperature of specimen *A* with a proflavin concentration of  $3 \times 10^{-6}$  g cm<sup>-3</sup>, and Fig. 2 shows similar spectra of specimen *B* with a proflavin concentration of  $2 \times 10^{-4}$  g cm<sup>-3</sup>. The prompt and delayed spectra were observed in identical geometry. A few hours before measurement of the prompt spectra the upper ends of the specimen tubes were broken to admit atmospheric oxygen and quench the proflavin phosphorescence.

Fig. 1. Prompt (curve 1) and delayed (curve 2) fluorescence spectra of  $3 \times 10^{-6}$  g cm<sup>-3</sup> proflavin in polymethyl methacrylate. Intensity in relative units.

Fig. 2. Prompt (curve 1) and delayed (curve 2) fluorescence spectra of  $2 \times 10^{-4}$  g cm $^{-3}$  proflavin in polymethyl methacrylate.

The maxima of the prompt and delayed fluorescence spectra of *A* are at  $\lambda_p^A = 486$  nm and  $\lambda_d^A = 498$  nm, respectively, and those of *B* at  $\lambda_p^B = 497$  nm and  $\lambda_d^B = 510$  nm, respectively. In each case there is a similar shift in the position of the fluorescence maximum of  $\Delta\lambda^A = 12$  nm and  $\Delta\lambda^B = 13$  nm, respectively. These results agree with those reported previously<sup>2</sup>, namely, that  $\lambda_d > \lambda_p$  and that  $\Delta\lambda (= \lambda_d - \lambda_p)$  is independent of the dye concentration. They appear to confirm that intermolecular triplet migration does not contribute to the effect, because otherwise a dependence of  $\Delta\lambda$  on dye concentration would be expected.

I wish to thank the British Council for a scholarship during 1965–66, my colleagues in the Manchester atomic and molecular physics group for their hospitality, and Dr. J. B. Birks for assistance with the presentation of this communication.

### New Method of Thickness Measurement with the Interference Microscope

THE optical path difference (OPD) between an object and the surrounding medium, as measured with a transmission interference microscope using axial illumination, is given by

$$\text{OPD} = T(\mu_o - \mu_m) \quad (1)$$

where  $T$  is the thickness of the object, and  $\mu_o$  and  $\mu_m$  are the refractive indices of the object and medium, respectively.

The usual method of measuring the thickness and refractive index of an object with the interference microscope is to make readings of the OPD with the object successively mounted in two media of different refractive index. The pair of equations thus obtained can be solved for  $T$  and  $\mu_o$  (ref. 1).

Nomarski has pointed out (personal communication) that the information necessary for the calculation of  $T$  and  $\mu_o$  can be obtained from measurements in a single medium, if the OPD is first measured in the usual way, and then with the object tilted relative to the optic axis of the microscope, using a universal stage. This note proposes an analogous but more convenient method,

namely, the measurement of the thickness and refractive index of a microscopical object mounted in a given medium, by means of two OPDs, one measured with axial parallel light, and the other with an oblique beam of light obtained by using only marginal rays from a wide-angle condenser. As the technique depends on the use of different parts of the aperture of the condenser, it may be called a two-aperture method of interference microscopy.

In Fig. 1, based on one given by Ingelstam<sup>2</sup>,  $T$  is the thickness of a plane-sided object of refractive index  $\mu_o$ , mounted in a medium of refractive index  $\mu_m$  and illuminated by a parallel beam of light inclined at an angle  $DEA$  to the optic axis  $AE$  of the microscope. The numerical aperture of the beam is given by  $NA = \mu_m \sin DEA = \mu_o \sin BEA$ , where  $CBE$  is the path of light passing through and refracted by the object, and  $DE$  is the path of the reference beam passing through the medium alone. The  $\text{OPD}_{NA}$  measured with this oblique illumination is given by

$$\text{OPD}_{NA} = (CB\mu_m + BE\mu_o) - DE\mu_m \quad (2)$$

It can be shown that

$$\text{OPD}_{NA} = T \left( \frac{\mu_o^2 - NA^2}{\mu_o \sqrt{1 - NA^2/\mu_o^2}} - \frac{\mu_m^2 - NA^2}{\mu_m \sqrt{1 - NA^2/\mu_m^2}} \right) \quad (3)$$

Designating the OPD measured with axial illumination as  $\text{OPD}_o$ , and combining equations (1) and (3), we obtain

$$\frac{\text{OPD}_o}{\text{OPD}_{NA}} = \frac{\frac{\mu_o}{\mu_o^2 - NA^2} - \frac{\mu_m}{\mu_m^2 - NA^2}}{\frac{\sqrt{1 - NA^2/\mu_o^2}}{\mu_o \sqrt{1 - NA^2/\mu_o^2}} - \frac{\sqrt{1 - NA^2/\mu_m^2}}{\mu_m \sqrt{1 - NA^2/\mu_m^2}}} \quad (4)$$

This expression is awkward algebraically, but knowing  $NA$  and  $\mu_m$  values of  $\text{OPD}_o/\text{OPD}_{NA}$  can be calculated for varying values of  $\mu_o$  and plotted graphically. From a measured value of the ratio  $\text{OPD}_o/\text{OPD}_{NA}$  the refractive index  $\mu_o$  of a microscopical object can be read off the graph and the thickness  $T$  obtained by substitution in equation (1).

Apart from the possibility of estimating both thickness and refractive index from measurements in a single medium, the two-aperture method has interesting theoretical implications.

Consider the case of a fixed biological object. This can be regarded as being composed of solid fibrils or lamellae, separated by interstices filled with immersion medium. With axial illumination the  $\text{OPD}_o = t(\mu_o - \mu_m)$ , where  $t$  is the effective thickness (that is, the thickness which the dry material would occupy if the interstices were eliminated), and  $\mu_o$  is the refractive index of the dry material. It is, however, equally valid to regard  $\text{OPD}_o$  as equal to

Fig. 1. Plane-sided object of refractive index  $\mu_o$ , mounted in a medium of refractive index  $\mu_m$  and illuminated by a parallel beam of light at an angle  $DEA$ .

$T(\mu_a - \mu_m)$ , where  $T$  is the true geometrical thickness of the object, and  $\mu_a$  is the "average" refractive index of the object plus any included immersion medium,  $\mu_a$  being defined by the expression

$$\mu_a = \frac{t\mu_o + (T - t)\mu_m}{T} \quad (5)$$

The two-medium method as conventionally used enables one to obtain the effective thickness  $t$  and the refractive index  $\mu_o$ , but not the geometrical thickness  $T$ . The significance of results obtained with the two-aperture method will depend on the physical state of the object. If the fibres and lamellae of which the object is composed are thick relative to the wavelength of the light used, and are separated by substantial amounts of medium, the  $OPD_{NA}$  measured with oblique illumination will be unaffected by the presence of the interstices, and the thickness and refractive index obtained by the two-aperture method will, as with the two-medium method, be  $\mu_o$  and  $t$ . If, however, the dry fibres of which the object is composed are of submicroscopic dimensions and the object appears microscopically homogeneous, the refractive index measured by the two-aperture method will be  $\mu_a$ , and the thickness will be the geometrical thickness  $T$ .

An important possibility which the two-aperture method offers is that of measuring the thickness and refractive index of a cell inclusion completely surrounded by cytoplasm. If  $T_1$  and  $T_2$  (Fig. 2) are the thickness of the cell and the inclusion, respectively, and  $\mu_m$ ,  $\mu_c$  and  $\mu_n$  are the refractive indices of the medium, cytoplasm and inclusion, respectively, the  $OPD_o$  of the cytoplasm relative to the medium is  $T_1(\mu_c - \mu_m)$ . By changing the immersion medium it is possible to estimate  $T_1$  and  $\mu_c$ , but the  $OPD_o$  of the nucleus (plus overlying cytoplasm) relative to cytoplasm alone always remains  $T_2(\mu_n - \mu_c)$ , and it is not possible to proceed further with the two-medium method<sup>2</sup>. Using the two-aperture method, it is, however, possible in principle to obtain  $T_1$ ,  $T_2$ ,  $\mu_c$  and  $\mu_n$  from measurements in a single medium provided both cell and inclusion can be taken to have plane-parallel sides (which will, regrettably, not often be the case). Measurements of the  $OPD_o$  and  $OPD_{NA}$  of cytoplasm relative to the medium will, as indicated previously, yield values for  $T_1$  and  $\mu_c$ . If one now measures the  $OPD_o$  and  $OPD_{NA}$  of the nucleus relative to the cytoplasm, one obtains an equation similar to equation (4), with  $\mu_n$  and  $\mu_c$  replacing  $\mu_o$  and  $\mu_m$ , respectively. From suitable tables one can as before read off the value of  $\mu_n$ , and obtain  $T_2$  by substitution in the equation  $OPD_o = T_2(\mu_n - \mu_c)$ .

Some calculated values of the ratio  $OPD_o/OPD_{NA}$  are given in Table 1, with various values of  $NA$  and assuming the medium to be either air ( $\mu_m = 1.0$ ) or water ( $\mu_m = 1.34$ ). It will be seen that the value of the ratio is very sensitive to change in  $NA$  and relatively insensitive to change in  $\mu_o$ , unless the value of  $NA$  is high. It is clearly necessary to determine the  $NA$  of the oblique illumination accurately and the condenser should preferably be well corrected, of high  $NA$ , and equipped with a movable pin-hole aperture precisely positioned at the first focal plane.

Fig. 2.  $T_1$  is thickness of the cell and  $T_2$  thickness of the inclusion, and  $\mu_m$ ,  $\mu_c$  and  $\mu_n$  are the refractive indices of medium, cytoplasm and inclusion respectively.

Table 1. NUMERICAL VALUES OF  $OPD_o/OPD_{NA}$  WITH VARYING  $NA$ ,  $\mu_n$  AND  $\mu_o$

$NA$	$\mu_m$	$\mu_o = 1.40$	$\mu_o = 1.50$	$\mu_o = 1.60$
0.3	1.34	0.9759	0.9774	0.9788
	1.0	0.9673	0.9695	0.9714
0.45	1.34	0.9445	0.9483	0.9515
	1.0	0.9245	0.9296	0.9340
0.90	1.34	0.7537	0.7721	0.7876
	1.0	0.6285	0.6544	0.6764
1.30	1.34	0.3082	0.3779	0.4278

In practice, various errors caused by non-ideal apparatus may be minimized by the application of what amounts to a null method, namely, the calibration of the  $NA$  of the oblique beam by determining the ratio  $OPD_o/OPD_{NA}$  with a standard object, the known refractive index of which is similar to that of the test specimen. Experiments with the two-aperture method will be reported elsewhere, but it is already clear that while with present equipment the two-aperture method is probably too insensitive to be usefully applied to most biological objects, the position is likely to change radically when interference microscopes of greatly increased precision<sup>4-6</sup> become available. The method may also prove useful in physics and industry.

I thank the U.K. Medical Research Council and the Science Research Council for research grants.

## BIOPHYSICS

### Synthesis of Nucleic Acids in Hair

A STUDY of the cells of the hair cortex of rats<sup>1</sup> showed that size changes of the nucleolus are not a reliable indication of changes in the rate at which cells are synthesizing proteins. The highest rate of protein synthesis was associated with the smallest nucleolar volume. It was not possible to demonstrate nucleoli in the cortical cells of the mid-keratogenous zone with specific stains for RNA.

Leblond *et al.* have obtained evidence that the nucleolus manufactures about 90 per cent of the RNA in a cell<sup>2</sup>. Biochemical investigations, especially those on the anucleolate Oxford mutation of *Xenopus*<sup>3</sup>, assign the synthesis of ribosomal RNA to the nucleolus. I have performed an experiment to discover if the anucleolate nuclei of the hair cortex synthesize RNA.

Twelve albino rats were injected subcutaneously with 0.4 mc./100 g body weight tritiated-cytidine (specific activity 990 mc./mmole). They were killed in pairs 1, 3, 12, 24, 48 and 72 h after the injection. Specimens of skin which bore actively growing hair were taken from the site of injection and the comparable site on the opposite side of the body. The specimens were fixed in Carnoy's fluid and autoradiographs prepared with 'Kodak AR 10' stripping film. Good autoradiographs were obtained after 6 days exposure of the sections from the site of injection. The observations reported here were made on a set of preparations from the injection sites.

One hour and three hours after the injection only one group of nuclei were not demonstrably radioactive. They were the cortical cells of the mid-keratogenous zone and higher levels of the follicles. The density of silver grains in the photographic emulsion over nuclei of the hair bulb was so high that it barely transmitted light. The pos-

sibility that this result was caused by diffusion of the  $^3\text{H}$ -cytidine away from the injection site is excluded by the radioactivity of the nuclei of the sheaths of the inner and outer roots. Evidently the synthesis of RNA by the anucleolate nuclei is depressed in these animals.

The cytoplasm was radioactive only in cells that had radioactive nuclei. After 1 h the density of silver grains over the cytoplasm was slight, after 3 h it was higher and after 12 h it was higher than that over most of the nuclei. After 12 h the cortical cells at the top of the keratogenous zone were radioactive.

The preparations that were killed 24 and 48 h after injection contained radioactive nuclei in the cortex and inner root sheath as far up the follicle as the upper bulb and mid-keratogenous zone respectively. These observations indicate that some  $^3\text{H}$ -cytidine was incorporated into nuclear DNA of matrix cells at the time of injection and was carried up the follicle as the cells migrated, in accordance with the time schedule proposed in earlier work<sup>4</sup>.

The cytoplasm of the cortical cells up to the end of the keratogenous zone was radioactive in the specimens killed after 12, 24 and 72 h. Because the cells continuously moved along the follicles from the matrix, RNA synthesized in the matrix was carried to higher levels. Cell division occurs only in the matrix, increase in cell size occurs only in the upper bulb<sup>5</sup>, and different proteins are manufactured at the top and bottom of the keratogenous zone<sup>6</sup>. We conclude that some RNA is associated with each of these different activities in turn and speculate that it may be non-specific ribosomal RNA.

These observations bear on the question of how the nucleolus and RNA participate in cell differentiation and metabolism.

### Mechanism of Radiation-induced Granulocytosis

AN early and transient rise in the number of circulating neutrophilic granulocytes is known to occur in the blood of various mammals, including man, after exposure to radiation<sup>1-5</sup>. Neither the aetiology of this radiation effect, however, nor the source of the mature neutrophils has been established. The evidence discussed in the present communication suggests that the granulocytosis is caused by the release of one or more pharmacologically active biogenic amines, which mobilize large intravascular reservoirs of mature neutrophils.

The action of radiation appears to be indirect, releasing into plasma a humoral agent which mobilizes neutrophils and which may be a normal constituent of the body<sup>6</sup>. It is perhaps significant, therefore, that epinephrine, one of several biogenic amines (others are norepinephrine, serotonin, and histamine) released by radiation exposure<sup>6</sup>, has long been known to increase the number of circulating neutrophils in man<sup>7-9</sup>. This effect also appears to be shared by norepinephrine, as shown by experiments on rats<sup>10</sup> and human subjects<sup>9</sup>.

In investigations with rats, we observed that biogenic amines could, in fact, induce a neutrophilia comparable with that caused by X-rays (Fig. 1). These experiments confirmed the effect of epinephrine and norepinephrine previously found in humans or rats and demonstrated that

serotonin and, to some extent, histamine could also produce a neutrophilia. Circulation levels usually reached a peak about 3 or 4 h after treatment, and were increased by a factor of about 3 for histamine, 5 for X-rays, and 6 to 8 for serotonin, epinephrine and norepinephrine.

These observations do not agree with two other investigations, one of which has reported that epinephrine, serotonin or histamine had no effect on the circulating level of neutrophils in rats<sup>10</sup>, and the other of which showed that histamine causes a neutropenia in humans<sup>11</sup>. In the former investigation, the absence of response may have been caused by the low doses of the amines administered (10  $\mu\text{g}$ ); norepinephrine, which produced a neutrophilia in the same investigation, was given in a much higher dose (200  $\mu\text{g}$ ). In the case of histamine neutropenia in humans, it should be noted that the mode of injection differed; the intravenous route was used in man, causing a rapid effect of short duration, whereas a subcutaneous injection of histamine (in oil), producing a more protracted effect, was used in the present investigation.

The large intravascular reservoirs of mature neutrophilic granulocytes, which are found adhered to, or marginated along, the walls of small blood vessels<sup>12,13</sup>, are readily mobilized by epinephrine<sup>14</sup>, presumably by increasing the velocity of blood flowing through the vessels<sup>13,14</sup>. Although regions of margination occur throughout the body, one of the main sites appears to be the lungs from which neutrophils can be released by both epinephrine and norepinephrine<sup>6</sup>. This intravascular source and presumed mode of action may also explain the effects of serotonin, which, like the catecholamines, has marked vasoconstrictor properties, particularly on the lung vasculature<sup>15</sup>. Such mobilization would not account for the effect of histamine, a known vasodilator, which we observed, unless it is assumed that the protracted effect of histamine "shock" induced the release of one or more of the other amines. This might explain why the effect of histamine was comparatively small, despite the relatively high dose injected (Fig. 1), and suggests that epinephrine, norepinephrine, and serotonin were the

Fig. 1. The effect of whole body X-irradiation (800 r), serotonin creatinine sulphate ( $12.4-24.7 \times 10^{-3}$  mM/kg), epinephrine ( $5.5-18.4 \times 10^{-3}$  mM/kg), norepinephrine hydrochloride ( $4.9-14.6 \times 10^{-3}$  mM/kg) and histamine hydrochloride ( $27.2-54.3 \times 10^{-3}$  mM/kg) on the number of neutrophilic granulocytes circulating in the peripheral blood of rats at various times after treatment. The experimental (●) and control (○) curves represent the serial examination of tail blood from 8 to 15 animals. The hatched areas signify the absolute range of values obtained. All amines were injected subcutaneously as a suspension in 0.5 ml. of olive oil; controls were given only oil. The number of neutrophils was computed from the total white blood cell count and from the per cent neutrophils found in smears stained with May-Grünwald-Giemsa; a minimum of 500 cells was scored for both procedures.

more important factors in the radiation-induced granulocytosis.

That intravascular reservoirs are the chief source of granulocytes mobilized by radiation appears to be consistent with existing knowledge. Bone marrow has in the past been considered to be a likely source of the neutrophils<sup>3,4</sup>. Experiments in which developing neutrophils were labelled with tritiated thymidine *in vivo*, however, have indicated that regions of haemopoiesis may not be the origins of the cells mobilized by radiation<sup>16</sup>. The re-entry of cells into the circulation from other extracellular sources has also been mentioned<sup>4</sup>, but evidence suggests that re-entry from intercellular spaces is unlikely, particularly in the quantities required at one time<sup>17</sup>. These various facts, although not eliminating bone marrow or other extracellular regions as a source, point to the intravascular reservoirs as the main sites of the mature cells mobilized by radiation and to biogenic amines as the mobilizing agents.

The role of pharmacologically active amines in radiation-induced neutrophilia is yet to be established. In separate experiments, we have seen that adrenalectomy has no influence on the effect of radiation, indicating that the adrenals are not necessary for the mobilization of neutrophils. We have also investigated the effects of various pharmacological antagonists to the biogenic amines. The antagonists used were the sympatholytic drug, dibenzylamine (25–50 mg/kg), the serotonin antagonists, lysergic acid diethylamide (25 µg/kg), dibenzylamine, morphine (25 mg/kg), cocaine (50 mg/kg), and the antihistaminic, mepyramine maleate (20–35 mg/kg); intraperitoneal injections were given 10 min before X-radiation or the respective amine. These antagonists not only failed to alter the effect of X-rays, but also failed to interfere with the action of the corresponding amine.

## PHYSIOLOGY

### Effect of Noradrenaline on Phosphatase Activity in Synaptic Membrane of the Rat Brain

THE classical experiments of Loewi<sup>1</sup> demonstrated the transmitter substance of the sympathetic nervous system to be adrenaline or noradrenaline<sup>2,3</sup>. Several further investigations have shown a transmitter substance to be present in the central nervous system (CNS), that is, the

hypothalamus, the central grey matter of mesencephalon and the area postrema<sup>4,7</sup>. Differential centrifugation of a CNS homogenate has demonstrated the presence of noradrenaline in the synaptic vesicles of the synaptic junction<sup>8–10</sup>. Electrophysiological investigation has revealed that electrical stimulation of amygdala or of terminals of bulbo-spinal neurones leads, in both instances, to a reduction of the noradrenaline content of certain areas of the brain<sup>11–13</sup>. The molecular basis for the action of noradrenaline in the CNS is, however, unknown. Previous investigations of the pharmacological action of noradrenaline, particularly on different enzyme systems<sup>14–16</sup>, have not provided the experimental evidence basic to a theoretical understanding of physiological events of depolarization and repolarization. The relationship of changes in the ion-flux across the synaptic membrane to the action of a transmitter substance has not been defined. Investigation (our report in preparation) of the distribution of phospholipids and glycolipids free from sialic acid in the sub-cellular fractions of hypothalamus revealed a preponderance of phosphatidyl-serine in the sub-mitochondrial fraction B–C<sup>19</sup> using the method of De Robertis *et al.*<sup>5,9</sup>. This discovery stimulated us to search for a possible function of phosphatidyl-serine in the synaptic endings. *In vitro* investigations revealed phosphatidyl-serine to be the only major lipid among phospholipids or glycolipids free from sialic acid of the CNS which binds the noradrenaline<sup>17</sup>.

Evidence has been presented for the presence in plasma membranes of liver of an alkaline phosphatase activated by magnesium and potassium ions and depressed by sodium ions<sup>18</sup>. This communication provides evidence for the presence of a similar phosphatase system in the CNS sub-cellular fraction which contains synaptic vesicles and nerve endings. The stimulatory effect of noradrenaline on the alkaline and neutral phosphatase in these sub-cellular fractions and the effect of several inorganic ions on this phosphatase-membrane system are shown.

Sub-cellular fractions were obtained by ultracentrifugation of homogenates of fresh rat brain from fourteen adult male Wistar rats of 200–225 g<sup>8</sup>. Electron microscopy of sub-cellular fractions was carried out as previously described<sup>19</sup>. Activities of neutral and alkaline phosphatase of the membrane fractions were estimated on the basis of the hydrolysis of *p*-nitro-phenylphosphate at pH 7.2 and pH 8.8 in *tris*-hydrochloric acid buffer (at 37° C<sup>18</sup>). The activities were expressed as mmoles of substrate hydrolysed/mg of membrane protein/min. Inorganic salts (sodium chloride, potassium chloride, caesium chloride, lithium acetate and magnesium sulphate) were of analytical grade and the noradrenaline (as bi-tartrate) was "a.m. pharmacopea Danica". To estimate the activity of phosphatase in the presence of only one inorganic ion (potassium, lithium) the corresponding salt of *p*-nitro-phenyl phosphate was prepared by ion exchange: 5 ml. of 0.1 molar disodium salt of *p*-nitrophenyl phosphate was added to 3 ml. of a suspension of 1.1 g of 'Dowex 50' (H<sup>+</sup> form). When the pH of the mixture appeared to be constant, the supernatant was isolated by centrifugation and 0.5 molar potassium hydroxide or 1 molar lithium acetate was added until the solution was at pH 7.0, yielding the potassium or lithium salts.

Tables 1, 1a and 1b demonstrate the activity of neutral and alkaline *p*-nitrophenyl phosphatase from different sub-cellular fractions of the CNS. Among the gradient fractions obtained by centrifugation of the crude mitochondrial fraction<sup>8,9</sup>, the fractions A, B and C which contain synaptic nerve ending and synaptic vesicles<sup>8,9</sup> had the highest specific activities. The activity at pH 8.8 is lower than at pH 7.2. In evaluating the effects of inorganic ions it is seen that potassium is the only ion which gives rise to activities higher than those of sodium, lithium, and caesium ions, and that activity is further increased by addition of potassium ions to a system containing sodium, lithium, and/or caesium ions. *p*-Nitrophenyl-phosphatase activities at pH 7.2 and 8.8 in subcellular fractions of homogenates of rat brain separated by ultracentrifugation<sup>21</sup>. Concentration of *p*-nitrophenyl-phosphate salts was 5 mmolar, and magnesium sulphate was 5.0 mmolar. Final concentration of additional salts was 48 mmolar (NA: 12 mM). Enzyme activity expressed as μmoles of *p*-nitrophenyl phosphate hydrolysed/mg of protein/min. All enzyme activities are results of four independent determinations. The activities are indicated with standard deviation of the mean. Content of sub-fractions of crude mitochondrial fraction (A-E): A, myelin, membranes of synaptic origin; B, synaptic vesicles and membranes and fragments of nerve endings; C, nerve endings; D, nerve endings; E, mitochondria, lysosomes, some nerve endings; F, microsomal fraction containing membraneous components with ribosomes; G, nuclear fraction with nuclei fragments some contaminating mitochondria, nerve endings. NA, Noradrenaline.

more, the presence of noradrenaline enhances the enzyme activities of sodium and/or potassium systems. This increased activity is maximally increased six times when noradrenaline is added to the pure system of sodium ions (B).

Previous experiments have demonstrated the involvement of phosphoprotein and probably phospholipids in the rapid exchange of phosphorus-32 induced by electrical stimulation of the CNS<sup>20,21</sup>. The exchange of phosphorus-32 provoked by electrical stimulation may be related to the activity of the membrane-bound ATPase which can be stimulated by magnesium ions<sup>23,24</sup>, because the activity of ATPase in the CNS contributes to the establishment of the uneven distribution of potassium and sodium ions in the CNS<sup>22,23</sup>. This may also be the chemical basis for the phenomena associated with electrical stimulation of the CNS. In contrast with the present findings of a *p*-nitrophenyl-phosphatase of sub-mitochondrial fraction A, B and C from the rat brain which are activated by potassium and magnesium ions and inhibited by sodium ions, the membrane-bound ATPase is activated by sodium ions<sup>23,24</sup>. The activity of ATPase should, therefore, be distinguished from the activity of *p*-nitrophenyl phosphatase of the CNS, which is activated by potassium and magnesium ions.

The present data which indicate activation of this phosphatase by noradrenaline imply that this hormone, liberated from the synaptic vesicles, may be a biological trigger mechanism leading to the exchange of potassium and sodium ions across the synaptic membrane, thus causing the electrical activity to continue in the post-synaptic dendrite.

The depressing effect of lithium ions on the activity of phosphatase, even in the presence of noradrenaline, could be part of the action of this drug on the CNS, which is used in the treatment of mania<sup>25</sup>. The effect caused by lithium ions seems to be opposite to that in the ATPase system<sup>24</sup>.

Finally, the high content of phosphatidyl-serine in the

biomembranes which contain the phosphatase which is activated by potassium and magnesium ions in CNS could control the action of noradrenaline, because this drug is specifically bound to phosphatidyl-serine<sup>20</sup>. Phospholipase D greatly enhances the activity of phosphatase apparently by degrading phosphatidyl-serine (our report in preparation).

### Demonstration of Nerve Terminals containing Adrenaline by a New Histochemical Technique

PREVIOUS reports on the presence of high concentrations of adrenaline in the frog heart have been confirmed and extended<sup>1</sup>. Using the histochemical technique of Falck in whole mount preparations of the atrium and sinus venosus of the frog, it was shown that tissue catecholamines were confined within the nerve fibre terminals of the sympathetic plexus. These findings were in agreement with a previous report<sup>2</sup>.

In the histochemical method of Falck<sup>3</sup> distinction between noradrenaline and adrenaline is based on the difference in time required for development of the fluorescent products after exposure to paraformaldehyde<sup>4,5</sup>; however, the optimal time in each case has been found to vary considerably among different laboratories and it appears to depend on the source of paraformaldehyde, environmental humidity, and other unknown local laboratory factors. For these reasons, a more specific technique was sought for the histochemical differentiation of fibres containing adrenaline from fibres containing noradrenaline.

After considerable experimentation a technique based on the well known formation of trihydroxyindole fluorescent products was developed, and this can be used for the specific demonstration of fibres containing adrenaline. The technique is as follows.

Whole mount preparations are stretched and placed on a slide and allowed to dry at room temperature for 10–15 min. The slides are then placed in a closed Coplin jar containing 2 g of iodine and are exposed to iodine fumes for 5–10 min. Finally, they are transferred to another

Coplin jar and exposed to fumes of ammonia for 45–60 sec. The exact time required for proper drying and exposure to iodine and ammonia was critical and had to be worked out for each preparation which was investigated.

A "tissue blank" is prepared by reversal of the order of exposure to iodine and ammonia which prevents the formation of adrenaline fluorescence products and permits the detection of non-specific tissue fluorescence. This increases greatly the specificity of the method.

With this technique, preparations from frog tissues including atrium, sinus venosus, mesentery and urinary bladder showed fluorescent fibres which were morphologically similar to those seen with the formaldehyde condensation method (Fig. 1). Conventional wide band excitation filters (BC 12, Corning 5–58) used in conjunction with green-yellow barrier filters at the ocular (Kodak 15) were satisfactory for demonstration of the fluorescence. The use of interference filters showed optimal excitation to occur with the 405 m $\mu$  line of the mercury lamp and the fluorescence colour was green to blue-green (500–520 m $\mu$ ) when observed with wide band barrier filters (Kodak 2E or 3). These findings correspond closely to the known excitation and fluorescent spectra of adrenolutin<sup>6,7</sup>. Surprising, however, was the fact that although no reducing agents were used, the fluorescent product was stable for more than 24 h.

When the same technique was used in tissues known to contain noradrenergic fibres (for example, rat mesentery) no fluorescent structures were seen. Thus adrenergic fibres can be detected in the presence of noradrenergic fibres which is not possible with the formaldehyde condensation technique. Similarly, as would be expected, structures containing serotonin (for example, rat mast cells) showed no fluorescence in these conditions.

Fig. 1. Fibres containing adrenaline in tissues of frog demonstrated with the trihydroxyindole reaction; (A) mesentery; (B) urinary bladder; (C) sinus venosus; (D) atrium.

Fig. 2. Atrium of guinea-pig treated with the trihydroxyindole reaction before (A) and after (B) exposure to adrenaline.

When tissues containing noradrenergic fibres were exposed to exogenous adrenaline, considerable uptake of the amine by tissues was found by chemical analysis by the method of von Euler and Lishajko<sup>8,9</sup>. When such tissues were examined histochemically by the method described here characteristic green to blue-green fluorescent fibres were seen (Fig. 2). No such structures were present in control, untreated preparations. This indicated that adrenaline was taken up within the noradrenergic fibres and further demonstrated the specificity of the technique.

In the iris of the rat this technique revealed blue fluorescent structures associated with the endothelium of the blood vessel similar to those seen with the formaldehyde technique after exposure of the iris to dihydroxyphenylalanine. The structures involved are not nerve fibres but are similar to those said to occur along blood vessels of the brain<sup>10</sup>. This phenomenon has been studied in some detail and the results will be reported elsewhere<sup>11</sup>.

When applied to frozen sections of the adrenal medulla of the hamster, the present technique did not produce any fluorescence in the cells containing adrenaline (centre of the gland); instead, a blue to blue-white fluorescence was obtained with the cells containing noradrenaline (periphery of the gland). A fluorescent reaction with noradrenaline cells of the adrenal medulla and no reaction with noradrenergic fibres has been previously reported when an adaptation of the trihydroxyindole method was employed in a histochemical procedure proposed by Carlsson *et al.*<sup>12</sup>.

Investigations carried out in this laboratory indicate that blue to blue-white fluorescent products can be obtained in noradrenaline fibres with a similar method provided that the specimens have been previously prepared with

procedures which release noradrenaline from tissue binding<sup>13</sup>. Thus, the essential part of the proposed method may be dependent on the presence of adrenaline in a relatively free form. In this connexion, it is noteworthy that ultracentrifugation has demonstrated that the adrenaline found in frog tissues was present mostly in the non-particulate fraction<sup>1</sup>.

Previous observations<sup>1,2</sup> and the present results indicate that the sympathetic neurohumour in the heart of frog (and in most other tissues of this species) is adrenaline rather than noradrenaline. This is in agreement with other observations<sup>14,15</sup>. It is now appropriate that such fibres containing adrenaline be called adrenergic while the term noradrenergic should be used to describe the fibres which contain noradrenaline and are widely distributed in the tissues of all higher vertebrates that have been examined<sup>16</sup>.

A complete method for the specific histochemical demonstration and differentiation of adrenergic and noradrenergic fibres using the trihydroxyindole reaction is now under development in this laboratory.

## Oculosympathetic Response to Circulatory Arrest

REPORTS of the role of the sympathetic nervous system in anoxic mydriasis are not clear. A generalized sympathetic discharge occurs during systemic anoxia<sup>1,2</sup>, but some published data suggest that the sympathetic nervous system plays no part in the pupillary dilatation which occurs during anoxia and ischaemia. Little or no dilatation of the parasympathectomized pupil was observed during anoxia in the presence of an intact sympathetic innervation<sup>3</sup>. The pupil which has had an interruption of sympathetic and parasympathetic innervation dilates during asphyxia<sup>4</sup>.

The right oculomotor nerve was sectioned intracranially in six adult cats. One to three weeks later under sodium pentobarbital anaesthesia a right lateral thoracotomy was carried out with complete occlusion of the ascending aorta and both venae cavae. After 6 min of circulatory arrest, a right preganglionic cervical sympathectomy was performed, and the great vessels were re-occluded for another 6 min. Transverse pupillary diameters were measured with a millimetre ruler before, during and after the vascular occlusions.

When an acute sympathectomy was superimposed on a chronic oculomotor section, the dilatation of the pupil

11	14	13	4	13	10	11	11	2	14

during ischaemia was abolished (Table 1). Dilatation still occurred when circulation was restored, presumably due to the effect of circulating neurohumours.

These data show that the chronically parasympathetically denervated iris was capable of further dilatation during circulatory arrest. This dilatation was not correlated with the changes in the arterial blood pressure (Fig. 1)

Fig. 1. Response of denervated pupil to circulatory arrest (cross-hatched area). ----, Parasympathetically denervated pupil; —, normal pupil; - · -, parasympathetically and sympathetically denervated pupil.

and occurred at a time when there was no flow of blood to the eye. This dilatation was abolished by cervical sympathectomy.

This investigation does not prove that the chief mediator of pupillary dilatation during circulatory arrest is the sympathetic nervous system, nor does it refute the idea of a balanced effect of both sympathetic and parasympathetic systems. Nevertheless, the sympathetic nervous system can produce extreme pupillary dilatation in an eye which has undergone chronic oculomotor nerve section, and such dilatation occurs at a time when no circulating neurohumours can reach the iris.

This investigation was supported in part by grants from the U.S. Public Health Service, the National Institute of Neurological Diseases and Blindness, and the Duke University Center for the Study of Aging.

## Respiratory Response to Carbon Dioxide in Man

In the course of our investigation on the respiratory regulation in man at high altitudes in the Himalayas<sup>1</sup> it was observed that the respiratory response of the Indian subject to carbon dioxide was lower than the European<sup>2</sup>. The unit of carbon dioxide response (pulmonary ventilation, l/min/mm mercury) is such that it should ultimately be related to the metabolic rate or the body weight. The body weight of the Indian subject was smaller (56 kg), and it was thought that his apparently low response to carbon dioxide may have been caused by his lower body weight.

Experiments aimed at investigating this relation were performed at sea level. No positive correlation between body weight and carbon dioxide response was obvious from the results, but the values for the response were consistently lower irrespective of the body weights in the Indian subjects.

The technique employed in this investigation was a simplified version of that developed at Oxford<sup>3</sup>. Briefly, the subject was seated comfortably in a chair and he breathed a mixture of oxygen, carbon dioxide and nitrogen from a large Douglas bag through a humidifier. The expirate was collected in a second bag. When a steady ventilation was reached the expirate was switched on to a third small bag and the collection was made for a timed period. During this period, the Rahn-Otis end tidal sample, which was drawn by water suction over a series of sampling tubes, was collected by mercury displacement. When the first bag was empty the subject was given the expirate bag to breathe from and his expired air was collected as before. Usually carbon dioxide was added to the second bag to raise the ventilation of the subject to about 40 l./min.

The volume of the expired air collected was measured in a spirometer and expressed as  $\dot{V}_{BTPS}$  (ventilation, body temperature pressure saturated), l./min. End tidal samples were analysed in a Lloyd-Gallenkamp analyser.

The relation between  $\dot{V}_{BTPS}$  and the atmospheric pressure of carbon dioxide ( $P_A\text{CO}_2$ ) (above threshold value) at any value of the atmospheric pressure of oxygen ( $P_A\text{O}_2$ ) is linear and the relation between the slope of these lines and  $P_A\text{O}_2$  is inverse. This respiratory response has been described<sup>4</sup> by the expression like  $\dot{V} = D(P_A\text{CO}_2 - B) [1 + A/(P_A\text{O}_2 - C)]$ , where  $B$  (mm of mercury  $P_A\text{CO}_2$ ) is the intercepts of these lines produced to  $P_A\text{CO}_2$  axis at zero ventilation, the asymptote  $D$  (l./min/mm of mercury  $P_A\text{CO}_2$ ) is the slope of the line in the complete absence of hypoxia, the parameter  $C$  gives a critical value of  $P_A\text{O}_2$  when the slope of the  $\dot{V} - P_A\text{CO}_2$  line approaches infinity and  $A$  (mm of mercury  $\text{O}_2$ ) describes the curvature of the hyperbola, that is, the hypoxia sensitivity.

With a few exceptions most of our results fit into this expression. Average values from six subjects for the parameters with their standard error are:  $B$ ,  $36.0 \pm 0.3$  mm of mercury  $\text{CO}_2$ ;  $A$ ,  $23.2 \pm 1.7$  mm of mercury  $\text{O}_2$ ;  $C$ ,  $30.9 \pm 9.0$  mm of mercury  $\text{O}_2$ ;  $D$ ,  $1.60 \pm 0.16$  l./min/mm of mercury  $\text{CO}_2$ . All these values fall within the range given by Cunningham, Patrick and Lloyd<sup>2</sup> except for  $D$ . Their value for the European subjects is on average  $3.98 \pm 1.35$  l./min/mm of mercury  $\text{CO}_2$ , which is significantly different

from the mean value obtained in our experiments on the Indian subjects.

In another series of experiments on sixteen subjects  $\dot{V}_E P_A\text{CO}_2$  lines were determined by breathing carbon dioxide in pure oxygen. When the upper linear part of the response was taken into account the mean slope of the lines was  $1.97 \pm 0.13$  l./min/mm of mercury  $\text{CO}_2$  and the extended intercept on the  $P\text{CO}_2$  axis was  $35.2 \pm 0.6$ . These values are in agreement with that obtained from the other series of full experiments. The value of  $D$ , however, is somewhat smaller than the slope of the  $\dot{V}_E P_A\text{CO}_2$  line on oxygen at 1 atmosphere. This is perhaps not unexpected, because the value of  $D$  corresponds to infinitely large oxygen pressure.

The body weights of these subjects ranged from 41 to 82 kg, and the range of oxie slope was 1.10 to 3.92. There was no correlation between the body weights and the response to carbon dioxide. The values for the parameter  $D$  and for the slope of the response to carbon dioxide line in high oxygen/kg body weight were  $30.1 \pm 4.4$  and  $36.4 \pm 3.0$  ml./min/mm of mercury, respectively.

The lower value of the oxie slope was not due to any greater resistance in the breathing system. The main difference between the Oxford experiments and our present experiments is in the groups of subjects. In our studies the subjects were Indians (Bengalis), while Cunningham *et al.*<sup>2</sup> used European subjects only. Thus these results demonstrate a significant difference of carbon dioxide response in different groups of subjects, if not a racial effect.

This conclusion appears to be supported by the observation on one Sherpa (Himalayan highlander) and one European subject at sea level whose oxie slopes of  $\dot{V}_E P_A\text{CO}_2$  lines were 1.30 and 3.72, respectively.

### Effect of Botulinum Toxin on Autonomic Nerves in a Dually Innervated Tissue

A HYPOTHESIS has suggested the existence of a cholinergic link in adrenergic transmission of postganglionic sympathetic nerve endings<sup>1</sup>. Much evidence has been presented in support of this hypothesis<sup>2,3</sup>. Botulinum toxin has been said to block sympathetic nerve transmission<sup>4</sup>. Botulinum toxin is known to block the release of acetylcholine from classically cholinergic nerve fibres<sup>5,6</sup>, and so it was suggested that sympathetic impairment by botulinum toxin reflects an action on the hypothetical cholinergic link in the sympathetic nerve fibre ending. Rather large concentrations of the toxin (20,000 to 50,000  $L.D_{50}$ /ml.) and long times (2–5 h) were, however, necessary to produce sympathetic blockage. It was therefore desirable to test the action of botulinum toxin on a dually innervated tissue so that effects on both classically adrenergic sympathetic fibres and classically cholinergic parasympathetic fibres could be observed in the same preparation.

The spontaneously beating rabbit sino-atrial node was isolated, perfused and prepared for stimulation of the intranodal autonomic nerve fibres and recording of spontaneous beat interval as previously described<sup>7</sup>.

Fig. 1. Influence of botulinum toxin on the biphasic chronotropic response of the sino-atrial node to excitation of intranodal autonomic nerve fibres. Beat interval records of A, control responses; B, responses after 90 min of perfusion with a solution containing 850  $L.D_{50}$ /ml. of botulinum toxin. The toxin produced complete blockage of the cholinergic response but did not reduce the adrenergic response. The inverted, two range scale indicates spontaneous beat interval in msec. The marker channel at the bottom of the records denotes periods of nerve stimulation.

Intranodal autonomic nerve fibres were stimulated every 180 sec throughout each experiment by a 10 sec burst of 10 V (+), 100/sec (rectangular wave pulses) with a pulse duration of 0.1 msec. Such stimulation produces a biphasic (negative, then positive) chronotropic response, which is mediated through the release of acetylcholine and nor-adrenaline<sup>8</sup>. In control conditions the response is stable for at least 4–6 h. Magnitudes of the cholinergic (negative) and adrenergic (positive) responses were quantified as previously described<sup>7</sup>, by measurement of the difference between the beat interval just before nerve stimulation and the maximal and minimal beat intervals, respectively, resulting from intranodal nerve stimulation.

Botulinum toxin was produced by anaerobic incubation of *Clostridium botulinum*, type E, strain Beluga. The toxin employed was present in the supernatant of the incubation medium after removal of the cells by centrifugation. The incubation medium was composed of 5 per cent tryptocase, 0.5 per cent peptone and 0.4 per cent glucose. To activate the toxin, 0.1 per cent trypsin was added and the mixture was incubated at 37° C for 45 min. This activated toxin solution contained 170,000 intraperitoneal mouse  $L.D_{50}$ /ml. The dosage of the toxin is expressed in these units. Except when diluting the toxin, it was stored in the cold, but not frozen. The activated toxin solution was incorporated in buffered Ringer-Locke solution in a known concentration and applied by continuous perfusion (approximately 3 ml./min).

Botulinum toxin was applied to seven preparations in concentrations of 170–17,000  $L.D_{50}$ /ml. In each preparation there was nearly complete, or complete, blockage of the cholinergic response to intranodal nerve stimulation. Characteristic of the action of the toxin was the slow progressive and irreversible nature of the cholinergic blockage produced. The greater the concentration of the toxin, the shorter was the time before complete blockage ensued. A complete cholinergic block occurred in 80 min with 850  $L.D_{50}$ /ml., and in 24 min with 17,000  $L.D_{50}$ /ml. Fig. 1 presents interval-meter records of chronotropic responses of a preparation before, and after, 90 min of perfusion with 850  $L.D_{50}$ /ml. As can be seen, there was complete blockage of the cholinergic response to intranodal nerve stimulation. Perfusion with 170  $L.D_{50}$ /ml. produced a slowly progressive cholinergic blockage. After 4 h of perfusion with this concentration the magnitude of the cholinergic response was reduced to 4.9 per cent of the control response. Thus, a 95 per cent blockage was produced with as little as 170  $L.D_{50}$ /ml. On the other hand, no adrenergic blockage

was observed in any preparation with up to 4 h perfusion with doses up to 3,400 *L.D.*<sub>50</sub>/ml. In one preparation perfused with 17,000 *L.D.*<sub>50</sub>/ml., there was an immediate reduction of the adrenergic response to 28 per cent of the control response, but this effect was not progressive and was immediately reversible when, after 30 min, the solution containing toxin was replaced with normal Ringer-Locke solution. This is in contrast with the complete, progressive and irreversible cholinergic blockage which had occurred in this preparation at this time. At 17,000 *L.D.*<sub>50</sub>/ml., the solution containing toxin constituted 10 per cent of the perfusate, and so it seems likely that this reversible effect is non-specific and is unrelated to the usual irreversible action of botulinum toxin. Specificity of the cholinergic blockage seen at lower concentrations was substantiated by treating two preparations with toxin solution which had been heated to 100° C for 15 min. This heat-inactivated toxin solution in a concentration of 0.5 per cent or 1.0 per cent (equivalent to 850 and 1,700 *L.D.*<sub>50</sub>/ml., respectively, of active solution) produced no cholinergic or adrenergic blockage.

These results do not represent a comprehensive examination of the effects of botulinum toxin, but they serve to emphasize a very important point which is already documented<sup>9-11</sup>; botulinum toxin is very effective in blocking parasympathetic nerve endings, but has little blocking action on postganglionic sympathetic fibres. It should be noted that the chronotropic response of the sino-atrial node to intranodal nerve stimulation depends on the excitation of postganglionic nerve fibres<sup>12</sup>, so that the present results are not related to any possible ganglion blocking action of botulinum toxin<sup>13</sup>.

These results are not easily compared with previous ones<sup>4</sup> because different conditions, tissues and toxin types were employed. Nevertheless, in this study botulinum toxin produced an apparently specific cholinergic blockage at much smaller concentrations than was used to block sympathetic function<sup>4</sup>. The great difference in the potency of botulinum toxin on parasympathetic and sympathetic nerves supports the classical concepts of cholinergic and adrenergic transmission.

The results presented here are exactly analogous to those obtained using hemicholinium in the same system<sup>7</sup>. Both hemicholinium, which blocks the synthesis of acetylcholine<sup>14</sup>, and botulinum toxin, which blocks the release of acetylcholine<sup>5,6</sup>, are effective in blocking the cholinergic response of the dually innervated tissue. On the other hand, even large concentrations of these agents do not produce adrenergic blockage. The results, therefore, do not support the earlier hypothesis<sup>1</sup>.

I thank Dr. Melvin W. Eklund of the U.S. Bureau of Commercial Fisheries for providing and assaying the botulinum toxin, and Professor Theodore C. West of the University of Washington for the use of his laboratories. This investigation was supported by a Public Health Service training grant.

## MICROBIOLOGY

### Stimulating Effect of Xylose on the Utilization of Galactose in some Fungi

THE wild type of the ascomycete *Ophiostoma multiannulatum* does not grow on the hexose D-galactose as a sole source of carbon although the fungus can respire on it<sup>1</sup>. In an investigation<sup>2</sup> of the ability of *Ophiostoma* to utilize galactose in the presence of glucose it was found that in such mixtures a certain amount of galactose, which depended on the concentration of glucose, was utilized for synthesis of cell material. Similar results were obtained when galactose was mixed with fructose, mannose or glycerol. It therefore seems that cells of the wild type can utilize galactose for growth only if another source of utilizable carbon or some metabolic intermediate of such a compound is present in the cells.

Fig. 1. Growth of *Ophiostoma multiannulatum*, strain 51 (mating type +), on 0.4 per cent arabinose (curve A) and 0.4 per cent rhamnose (curve B). At the time indicated by the arrows the cultures were divided into two halves and to one of these 0.4 per cent galactose was added (curves A<sub>1</sub> and B<sub>1</sub>). Growth was measured photometrically at 610 mμ.

In a later study of the growth of the wild type strain 51 (mating type +) of *Ophiostoma multiannulatum* on various pentoses it was found that an addition of galactose to cultures growing on L-arabinose or L-rhamnose resulted immediately in an increased rate of growth which was shortly followed by complete cessation (Fig. 1). A culture on 0.4 per cent D-xylose also grew more rapidly when galactose was added (Fig. 2), but in this case the growth continued until both sugars were used up. In further growth experiments with mixed sugars the concentration of galactose was kept constant while the concentration of xylose was varied. A concentration of 0.004 per cent xylose, although too low to support measurable growth, nevertheless made it possible for the culture to grow on galactose (Fig. 3, curve C). The xylose is used simultaneously and the growth stops when the concentration of this sugar becomes limiting. As illustrated in Fig. 3, curve D, the addition of more xylose to a culture which had grown on 0.4 per cent galactose + 0.004 per cent xylose resulted in immediate resumption of growth. To obtain complete utilization of galactose it was necessary to add xylose at such a concentration that the ratio between galactose and xylose was approximately 40 to 1.

A number of different mutant strains of *Ophiostoma multiannulatum*, which use galactose as a sole source of carbon, have been isolated<sup>2</sup>. One of these strains (No. 5121) grows very slowly on galactose after a long lag phase. The addition of xylose at a concentration of 20 mg/l. to a

Fig. 2. Growth of strain 51 (mating type +) on 0.4 per cent xylose (curve C). At the time indicated by the arrow the culture was divided into two halves and to one of these 0.4 per cent galactose was added (curve C<sub>1</sub>).

medium containing 0.4 per cent galactose increased the growth rate and shortened the lag phase.

The promoting effect of xylose on the utilization of galactose was also tested in some other fungi. *Ophiostoma ulmi* and *Aspergillus niger*, which both grow rather slowly on galactose, responded with a marked increase in the rate of growth when the galactose was supplemented with traces of xylose. *Ophiostoma piceae* was found to grow faster on a mixture of 0.4 per cent galactose + 0.002 per cent xylose than on 0.4 per cent glucose. On the other hand, the growth on galactose of four *Coprinus* species was unaffected by xylose.

Relatively little is known about the metabolism of galactose in fungi, with the exception of yeasts<sup>3,4</sup>. It is

Fig. 3. Growth of strain 51 (mating type +) on 0.004 per cent xylose (curve A), 0.4 per cent galactose (curve B), 0.4 per cent galactose + 0.004 per cent xylose (curve C) and 0.4 per cent galactose + 0.004 per cent xylose with another addition of 0.004 per cent xylose at the time indicated by the arrow (curve D).

therefore difficult to interpret the observed xylose effects in biochemical terms. In *Ophiostoma multiannulatum*, galactose is readily taken up by all strains tested<sup>2</sup>, but conversion to glucose intermediates appears to be blocked in the wild type strains. Yet even in these wild type strains some metabolism of galactose undoubtedly occurs since galactose is respired<sup>1</sup>. It is possible that a metabolic product of xylose may function as a cofactor for the conversion of galactose to glucose intermediates. Another possibility is that xylose can help the cells to overcome a block in the metabolism of galactose by preventing the accumulation of some growth inhibiting compound.

Enzyme studies on the metabolism of galactose in *Ophiostoma multiannulatum* are in progress.

### Synthesis of Seleno-amino-acids in Cell Free Extracts of *Candida albicans*

SELENIUM, long considered an element toxic to the majority of living organisms, may be of physiological importance in various animals as an indispensable part of the diet<sup>1-5</sup>. It may replace the sulphur atom in sulphur amino-acids<sup>6-14</sup> in the proteins of plants, animals and micro-organisms<sup>15-18</sup>, and could stimulate cell division in a filamentous mutant of *Candida albicans*<sup>19</sup>. This stimulation has been related to the replacement of sulphhydryl groups in the composition of the cell wall with —SeH groups, the greater stability of which can overcome in the filamentous mutant the deficiency in protein-disulphuro-reductase<sup>20</sup>, an enzyme indispensable to plastification of the cell wall<sup>21</sup>.

Identification of selenocysteic acid and cysteine in the enzyme hydrolysate of *Candida albicans* cells cultivated in the presence of sodium selenite labelled with selenium-75 (ref. 14) would therefore be of special physiological significance.

The routes by which seleno-amino-acids are synthesized are still unknown, and there is close structural and chemical analogy between selenium and sulphur compounds, so we decided to investigate whether the reactions involved in the synthesis of sulphurated amino-acids could lead to the synthesis of analogues containing selenium.

Two routes are at present known for the incorporation of inorganic sulphur into organic bonds: these are the reversibility of the desulphydration of cysteine<sup>22-24</sup> and the reversibility of the desulphination of cysteine-sulphinic acid<sup>25,26</sup>. The synthesis of cysteine-sulphinic acid from sulphite, pyruvic acid and glutamic acid occurs in *Proteus*<sup>27</sup> through direct enzyme condensation of the first two compounds, with formation of sulphinylpyruvic acid which is then transaminated with glutamate. (The efficiency of this metabolic route has been established by Shepherd in *Aspergillus nidulans*, using parathiotrophic mutants<sup>28</sup>.)

The present investigations have been carried out to demonstrate the efficiency of this metabolic route in *C. albicans* and the possibility of replacing the sulphite with selenite in the direct condensation reaction with pyruvic acid, and consequent synthesis of seleno-amino-acids.

Cells of *Candida albicans*, strain RM 806, resistant to high concentrations of selenite, capable of reducing it to

amorphous metallic selenium<sup>19</sup> and of incorporating it into their own proteins<sup>14</sup>, have been cultivated in medium GGY<sup>19</sup>, collected after 48 h incubation at 28° C by centrifugation and disintegration in a 'Nike X-press' (Eskilstuna, Sweden) and cooled in acetone-dry ice. The material which was collected was suspended in an equal volume (w/v) of 0.066 molar phosphate buffer, pH 7.2, and centrifuged at 16,000g for 10 min at +2° C. The supernatant liquid was used as an enzyme in the test.

The incubation mixture used for the enzyme assays contained 10 mmolar sodium glutamate and sodium pyruvate, 1 mmolar pyridoxalphosphate, 10 mmolar sodium sulphite or labelled sodium selenite, and 5.0 ml. of cell-free extract in a final volume of 10.0 ml. Incubation was carried out at 37° C for 5 h, and then blocked by the addition of 1 ml. of 15 per cent trichloroacetic acid. After centrifugation at 16,000g for 10 min at +2° C, the trichloroacetic acid was extracted from the supernatant liquid with ethyl ether.

Fig. 1. Chromatographic analysis of deproteinized incubation mixtures on a column of 'Dowex 50W × 4', 200–400 mesh, H<sup>+</sup> form. Speed of elution was 2.0 ml./min; 10.0 ml. fractions were collected. Radioactivity was measured on 1.0 ml. samples with a well scintillation counter radioanalyser. Arrows show change in molarity of hydrochloric acid (1.1 molar/2.5 molar/4.0 molar).

After assays of efficiency of the enzyme preparation for the synthesis of cysteine and cystine in the presence of sodium sulphite had been carried out by means of the chemical determination of these amino-acids<sup>20</sup>, the mixture incubated with labelled sodium selenite was fractionated by chromatography on columns of 'Dowex 50W × 4', 200–400 mesh, in the H<sup>+</sup> form (15.0 cm high and 2.5 cm in diameter). Water (250 ml.), followed by a solution of hydrochloric acid of increasing molarity (1.1, 2.5, and 4.0 molar, 450 ml. of each), were used as the eluents. The radioactivity of each fraction was determined, and the radioactive fractions were concentrated under vacuum and chromatographed on Whatman No. 1 paper.

With the water the labelled selenite was eluted along with other salts. With 1.1 molar hydrochloric acid a peak in the fractions was obtained towards 400 ml., in the area which corresponded to selenomethionine<sup>16</sup>. Two radioactive peaks were eluted with 2.5 molar hydrochloric acid, one in the first fractions, for which no references are known, and another in the central fractions where, according to Blau<sup>13</sup>, selenocystine appears. Finally, 4.0 molar hydrochloric acid gave a rapid appearance of a fourth radioactive peak (Fig. 1). Paper chromatography of the concentrated radioactive fractions revealed the presence of ninhydrin-positive substances, radioactive on scintillometric analysis, the  $R_F$  values of which are given in Table 1. The close similarities between the  $R_F$  values of methionine and of the compound eluted with 1.1 molar hydrochloric acid are obvious, while the compounds eluted

with 2.5 molar hydrochloric acid have  $R_F$  values near to but not identical with those of cysteine acid, and the compound eluted with 4.0 molar hydrochloric acid has an  $R_F$  which corresponds to that of cystine.

The  $R_F$  of the compound eluted with 1.1 normal hydrochloric acid is almost identical to the  $R_F$  of synthetic selenomethionine, obtained with the same solvents by Tuve and Williams<sup>12</sup>.

Table 1.  $R_F$  VALUES OF SOME SULPHUR CONTAINING AMINO-ACIDS AND OF RADIOACTIVE SELENIUM COMPOUNDS ISOLATED ON 'DOWEX 50'

Amino-acids	$R_F$	Eluted radiocompounds	$R_F$
Methionine	75.5	1 (1.1)	74.5
Cysteine	58.0	2 (2.5)	50.3
Methionine sulphoxide	56.7	3 (2.5)	50.2
Cysteic acid	48.0	4 (4.0)	34.0
Cystathionine	37.0		
Cystine	35.0		

Paper was Whatman No. 1, solvent was tertiary butanol, normal hydrochloric acid and water (70.0 : 6.7 : 23.3); spots were developed with 1 per cent ninhydrin in water saturated *n*-butanol. Figures in brackets are molarities of hydrochloric acid.

Direct paper chromatographic analysis of the deproteinized incubation mixture (Fig. 2) has revealed four ninhydrin-positive spots with  $R_F$ s identical to those of methionine, glutamate or alanine, methionine sulphoxide and cysteic acid, respectively.

These spots were always found to be radioactive, with a higher intensity in the case of spot B caused by glutamic acid and alanine (Fig. 2). Autoradiography of chromatograms on which labelled sodium selenite was placed to migrate beside the sample has permitted confirmation that the radioactivity of this spot is caused by the selenite, which has an  $R_F$  identical to those of glutamic acid or alanine.

In conclusion, the *in vitro* enzyme synthesis of selenomethionine seems to be certain, while the synthesis of selenocysteine is likely, although this compound has not been isolated, probably because of its extreme lability.

Fig. 2. Chromatography on Whatman No. 3 paper of a deproteinized incubation mixture. (1) Standards used were methionine, cysteic acid and cystathionine (from top to bottom); (4) A, B, C and D were samples of the incubation mixtures; (2) sample of incubation mixture plus methionine sulphoxide and cystine standards; (3) sample of incubation mixture plus methionine and cysteic acid standards. Solvent and ninhydrin solutions were as in Table 1.

A radioactive compound with  $R_F$  identical to that of cysteine acid has been identified by direct paper chromatography, which suggests that spontaneous oxidation of the seleno-amino-acids of the test sample may occur, partially in the case of selenomethionine and almost completely in the case of selenocysteine. This is also confirmed by the demonstration of a radioactive compound with an  $R_F$  identical to that of cysteine, in the eluate of 4.0 molar hydrochloric acid. Finally, another indirect proof of the presumed synthesis of selenocysteine is given by the fact that in the system used the synthesis of selenomethionine is constant, which necessarily presupposes that of selenocysteine.

Our results are important for the understanding of the mechanism of synthesis of organic selenium compounds, although all the steps involved are not fully explained. Furthermore, they clearly show that sulphite could be replaced by selenite in the condensation with pyruvic acid, which could, among the extensive biochemical relationships between sulphur and selenium compounds, be either an antagonism at the membrane level<sup>30,31</sup>, or possibly replacement of the sulphur atom by an atom of selenium in organic compounds<sup>6-18</sup>.

The incubation mixture used apparently permitted the formation of cysteine and cystine but not of methionine, because a complex enzyme methylating system is generally necessary for synthesis of the latter<sup>32-34</sup>. Thus, although it is possible that all the factors necessary for synthesis of methionine were present in the "crude" enzyme preparation used, it is necessary to investigate its mechanism more thoroughly, and research is now in progress.

## IMMUNOLOGY

### Thymectomy and Anaphylactic Antibody in Rats infected with *Nippostrongylus brasiliensis*

It has been reported that neonatal thymectomy causes a defect in the production of "IgA" antibody in the rat. Arnason *et al.*<sup>1</sup> have shown that thymectomized rats immunized with bovine serum albumin (BSA), diphtheria toxoid, or heat-killed *Salmonella typhosa* produce comparatively small amounts of anti-BSA precipitating antibody and anti-diphtheria toxin (both largely IgA antibodies) but produce average amounts of anti-typhoid "O" agglutinin (IgM antibody) and of anti-BSA haemagglutinin (IgG antibody). In the present investigation, the production of anaphylactic antibody was compared in neonatally thymectomized and sham-operated rats infected with the intestinal nematode, *Nippostrongylus brasiliensis*. This infection normally results in high titres of reagin-like antibody to worm antigen<sup>2</sup>. The object of the present experiments was to determine whether the immunological deficit produced by neonatal thymectomy affects the production of anaphylactic antibody and the acquisition of immunity to infection with *N. brasiliensis*.

Sprague-Dawley rats were thymectomized or sham-operated within 24 h of birth<sup>3</sup>. All animals were weaned at 31 days, separated by sex, and kept under standard conditions. Thirteen thymectomized and ten sham-operated rats, 6-10 weeks of age, were inoculated subcutaneously with 1,000 larvae of *N. brasiliensis* (NIH strain). The infective larvae were cultured as described by Weinstein and Jones<sup>4</sup>. To control possible bacterial infection, all rats were given oxytetracycline hydrochloride in their drinking water (50 mg/l.); the drug was replaced three times a week. One month after the primary infection each rat was reinfected with 2,500 larvae. Egg-counts were done on the faeces of infected animals<sup>5</sup> between the sixth and eleventh days of infection. All animals were autopsied at the end of the experiment and examined grossly or histologically for thoracic thymus tissue.

Fig. 1. Counts of the number of eggs/g of the faeces of groups of thymectomized (○), sham-operated (●) and normal rats (×) after a primary infection with 3,000 larvae of *N. brasiliensis*. The number of rats per group is shown in brackets.

Rats were bled from the retro-orbital sinus or from the heart before infection, 1 month after the first infection and 6 days after the second infection. Sera were stored at  $-20^{\circ}\text{C}$ . Anaphylactic antibody titres of the sera were determined by passive cutaneous anaphylaxis (PCA) in

normal Sprague-Dawley rats (150–200 g). Antigen for the PCA tests was prepared from adult worms collected from the small intestine of rats 10 days after subcutaneous infection with 3,000 larvae of *N. brasiliensis*. The worms were washed by repeated sedimentation in saline, and then homogenized in buffered saline (pH 7.2) in a Potter-Elvehjem glass homogenizer packed in ice. The homogenate was centrifuged at 1,000g for 10 min and the supernatant fluid (2 mg protein/ml.) used as antigen. PCA tests were carried out as follows. Rats were injected intradermally with 0.1 ml. of serum diluted in buffered saline 1/2, 1/3, or 1/5 to 1/2,000. Forty-eight hours later, 0.1 ml. of worm antigen mixed with 0.9 ml. 1 per cent Evans blue dye was injected intravenously. The rats were killed with ether 30 min later, skinned, and the reflected surface of the skin examined for extravasated dye.

Before evaluating the antibody response of thymectomized rats infected with *N. brasiliensis*, a preliminary experiment was done to test the effect of thymectomy on the course of primary infection. It was found that thymectomy did not inhibit establishment of the infection or egg production by the worms (Fig. 1). The typical pattern of spontaneous termination of egg production and elimination of worms from the small intestine was delayed, however, by a few days in thymectomized as compared with sham-operated and control rats.

The anaphylactic antibody response of thymectomized and sham-operated rats following a primary infection with *N. brasiliensis*, and a challenge infection 1 month later, was determined by PCA tests as already described. Anaphylactic antibody was not demonstrable in the sera of uninfected rats. Four weeks after primary infection only two out of ten thymectomized rats had PCA titres as high as 1/80, whereas seven out of ten sham-operated rats had PCA titres of 1/80 to 1/320 (Table 1). Six days after the second infection, five out of eight thymectomized rats showed no increase in PCA titre, while the three others showed increases in titre ranging from 1/30 to 1/450; residual thymus was found in two of the latter three animals. In contrast, seven out of eight sham-operated rats bled 6 days after the second infection had increased PCA titres (maximum 1/1,000). Thus, the PCA titres of the thymectomized rats were lower than those of the sham-operated rats both before and especially after a second infection.

Table 1. RECIPROCAL OF PCA TITRES OF SERA FROM THYMECTOMIZED AND SHAM-OPERATED RATS AFTER A FIRST AND SECOND INFECTION WITH *N. brasiliensis*

Rat No.	Treatment	Titres after		State of thymus
		First infection*	Second infection†	
9	Thymectomized	<2	<2	None
1		<3	<5	None; rat wasted
14		<3	Not done	None; rat wasted
3		<3	10	None
4		<3	75	Some present

		320	320	Intact

\* Four weeks after first infection.

† Six days after second infection.

Observations were also made on the output of eggs in the faeces of thymectomized and sham-operated rats after a second infection with *N. brasiliensis* (Fig. 2). Thymectomized rats infected for the second time passed few eggs, and sham-operated rats passed none; the output of eggs

Fig. 2. Counts of the number of eggs/g of the faeces of groups of thymectomized (○) and sham-operated (●) rats following a second infection with 2,500 larvae of *N. brasiliensis*. Normal rats (×) were given a primary infection as a control.

was normal in rats given a primary infection with larvae from the same batch. The low output of eggs in the thymectomized rats was taken to indicate strong resistance to the second infection because, as already demonstrated (Fig. 1), thymectomy does not inhibit the production of eggs in a primary infection. Thus, despite relatively low titres of circulating anaphylactic antibody, thymectomized rats resisted a second infection almost as well as did sham-operated rats which had relatively high titres of such antibody. These results do not exclude the possibility that anaphylactic antibody bound to tissue plays a part in resistance to reinfection with *N. brasiliensis*.

## HAEMATOLOGY

### Reduction of Methaemoglobin in Haemoglobin Samples using Gel Filtration for Continuous Removal of Reaction Products

EVEN a small degree of oxidation of haemoglobin to methaemoglobin, such as occurs in the transport and storage of frozen red cells, interferes with the study of its oxygen dissociating properties. When abnormal are separated from normal haemoglobins, even more methaemoglobin accumulates during the manipulations involved. The methaemoglobin may be efficiently reduced by passing a haemolysate of such a partly oxidized

sample by means of gel filtration through a band of reducing agent. Advantages of this method are that the methaemoglobin constantly encounters fresh reducing agent and that the continued elution quickly removes the haemoglobin formed from excess reagent. These factors are important when reduction is by dithionite, as side reactions can then destroy the haemoglobin. A similar principle can be applied to the oxidation of cytochromes<sup>1</sup>, and to the conversion of the aldimine form of aspartate aminotransferase (*E.C.* 2.6.1.1) into the amino form by transamination with an amino-acid<sup>2</sup>. The continuous removal of the  $\alpha$ -oxoacid formed is particularly important in the latter case because the position of equilibrium is unfavourable to formation of the amino form.

The efficacy of the method can be demonstrated with the methaemoglobin formed by oxidizing a fresh haemolysate. A column of 25 x 1.5 cm of cross-linked dextran gel particles ('Sephadex G-25', fine) was equilibrated with 20 mM phosphate buffer of pH 7.0. A solution of 12 ml. sodium dithionite in 1 ml. of this buffer was run on to the column, followed by 0.2 ml. of buffer. A sample of 2 ml. haemolysate (about 5 per cent haemoglobin) was oxidized to methaemoglobin with about 3 mg of sodium ferricyanide and was added in turn to the column. The haemoglobin was eluted with buffer. The course of the reactions was easily followed by observing the colour changes. The methaemoglobin separated from the ferricyanide which it left behind as a more slowly moving yellow band. As the protein entered the dithionite zone the brown methaemoglobin was reduced to purple haemoglobin. It then turned orange-red as it moved out of the dithionite and bound the oxygen dissolved in the buffer farther down the column. As the volume of buffer thus depleted of oxygen increased, the change of colour from purple to orange-red moved away from the dithionite band. Oxygenation was completed before the haemoglobin was collected from the bottom of the column. The whole procedure took less than 20 min.

Haemoglobin treated in this way showed an absorption spectrum from 450 to 700 m $\mu$  indistinguishable from that of the untreated haemoglobin. Three determinations of the degree of oxygenation of the treated haemolysate at each of two fixed oxygen partial pressures, at 38° C, showed that this property was unaffected by the treatment. The rate of formation of methaemoglobin at 38° C and pH 7.0 was similar in treated and untreated samples. These experiments showed that haemoglobin suitable for study of its properties had been simply regenerated from methaemoglobin.

### Platelet Electrophoretic Behaviour in Thrombasthenia

Blood platelets from patients with thrombasthenia do not adhere to glass in either a whole blood system or in a platelet-rich plasma system to which adenosine diphosphate (ADP) has been added, and they fail to adhere to each other in the presence of ADP, noradrenaline, thrombin, or connective tissue extract<sup>1,2</sup>. The electrophoretic mobility of thrombasthenic platelets has been shown to be normal<sup>3</sup>, but hitherto the changes in mobility which normally occur in the presence of aggregating agents<sup>4</sup> have not been studied in thrombasthenia.

We have investigated two thrombasthenic patients, a boy aged 12 years and a girl aged 16, using the technique

described by Hampton and Mitchell<sup>4</sup>. (The boy was Case 1 in a previous report<sup>1</sup>; we thank Dr. Katharine Dormandy for permission to study the other patient.) Platelet electrophoretic mobility was measured on samples of platelet-rich citrated plasma (PRCP) diluted ten times with platelet-poor plasma (PPP).

The platelet electrophoretic mobility of the two patients was 1.23 and 1.24  $\mu$ /sec/V/cm, respectively, and in each patient the mobility was the same before and after contact with a non-siliconized glass surface<sup>5</sup>. In neither case was there any change in mobility after incubation with ADP (added to give final concentrations of 0.05–5.0  $\mu$ g/ml.), noradrenaline (final concentrations 0.05–0.5  $\mu$ g/ml.) or a connective tissue extract.

These are the first subjects we have investigated in whom changes in platelet mobility could not be induced by glass contact or by these agents; the changes in the mobility of normal platelets can, however, be abolished by compounds which interfere with sulphhydryl groups<sup>6</sup>. In the presence of sulphhydryl blocking agents, normal platelets behave like those from the two patients with thrombasthenia, and when additional SH groups are provided by adding *L*-cysteine the normal electrokinetic behaviour of the platelets with aggregating agents is restored. Extra sulphhydryl groups were therefore made available to the thrombasthenic platelets by incubation of the PRCP–PPP mixture with 10<sup>-4</sup> molar *L*-cysteine at room temperature for 15 min. This had no effect either on the basic platelet mobility or on the response to ADP.

The PRCP from one of the patients was incubated with fresh PPP from a normal subject for 30 min at room temperature: the platelets remained unresponsive to ADP.

It has been suggested<sup>4</sup> that the increase in surface charge which is normally induced by low concentrations of aggregating agents results from the adsorption of ADP by the platelets: this can be exogenous ADP which has been added to the suspending medium or endogenous ADP released from within the platelet by noradrenaline, thrombin, or collagen. As we found no electrokinetic response to either exogenous ADP or to noradrenaline in the two patients, and as the release of ADP from thrombasthenic platelets has been shown to occur normally<sup>2</sup>, we conclude that in thrombasthenia there is a defect in the binding of ADP to the platelet surface. Because the thrombasthenic platelets had the same mobility before and after glass contact, this conclusion is also consistent with the previous suggestion<sup>5</sup> that in normal subjects the reduction of platelet mobility on contact with a non-siliconized glass surface arises from the removal of adsorbed ADP. Our results also provide further evidence that the change in electrophoretic mobility induced by aggregating agents is due to a change in surface charge and not to a change in shape or size of platelets, for shape changes in response to ADP have been shown to be normal in thrombasthenia<sup>7</sup>.

## PATHOLOGY

Effects of Oestrone-17 $\beta$ -thiol on the Endocrine Organs of the Castrated Female Rat

THE biological properties of oestrone-17 $\beta$ -thiol (3-hydroxy 1,3,5 (10) oestratriene-17 $\beta$ -thiol) were compared with those of oestradiol-17 $\beta$ . Oestrone-17 $\beta$ -thiol has already been synthesized<sup>1-3</sup>, but no report of its biological properties has been published. We have investigated the effect of this compound on the weight of the endocrine organs, vaginal smear, and on adeno-hypophyseal histology in the castrated female rat. Adult animals were ovariectomized 15 days before the start of the experiments. Details of the investigation are given in Table 1a and b. All doses were compared with the same amounts of oestradiol-17 $\beta$ .

At a dose of 10  $\mu$ g/100 g of body weight (twenty to fifty times the necessary dose of oestradiol-17 $\beta$  for maximal uterine growth), no significant effect on the uterus or

vaginal smear could be demonstrated. A greater dose, of 40  $\mu$ g/100 g of body weight, caused an increase in uterine weight and an oestrous vaginal smear. The hypophysis, however, showed only slight change in weight and no effect on the thymus was visible. With the highest dose tested, 200  $\mu$ g/100 g of body weight, practically maximal uterine weight was obtained, but again the thymus maintained the same weight as the control animals, and the difference between the two drugs is highly significant at this level.

On the other hand, the smallest dose (10  $\mu$ g/100 g of body weight) which was ineffective in the production of vaginal epithelium or uterine changes caused the disappearance of castration cells from the adeno-hypophysis.

The results indicate that the sulphhydryl group at the  $\beta$  position of the seventeenth carbon atom of the oestrone molecule has not only reduced the oestrogenic potency, but has also affected other properties generally associated with the oestrogenic molecule such as the ability to

promote growth of the adenohypophysis and atrophy of the thymus. It is clear that, even when a definite oestrogenic effect was elicited, the weight of the thymus was not affected. The atrophy of the thymus after administration of oestrogen is caused through more than one mechanism<sup>4</sup>; experiments to determine the action of oestrone-17 $\beta$ -thiol on adrenal function and release of ACTH are necessary, even considering that the adrenal gland weight was not affected. The fact that even without showing any oestrogenic effect the drug was able, in small doses, to block the appearance of castration cells in the adenohypophysis, can be of some importance. We have not determined whether this histological picture corresponds to low concentrations of pituitary gonadotrophin.

### 1,6-Dibromo-1,6-dideoxy-dulcitol: a New Antitumoral Agent

AMONG the  $\alpha,\omega$ -substituted sugar-alcohols the dibromo derivatives represent a special group because of their biological properties<sup>1</sup>. The first dibromo-hexitol introduced into clinical use, the dibromo-mannitol ('Myelobromol'<sup>®</sup>), has myelotoxic effects<sup>2</sup>. Its diastereoisomer dibromo-dulcitol (DBD) revealed, in pharmacological experiments, remarkable qualities.

DBD was prepared by treating dulcitol with aqueous hydrobromic acid saturated with gaseous hydrogen bromide at a temperature less than 0° C. On dilution of the reaction mixture with water, crude DBD precipitated to give a yield of about 70 per cent. Recrystallization from methanol gave colourless plates, of melting point 186°–190° C (decomp., corr.). Analysis showed 23.8 per cent carbon, 4.1 per cent hydrogen, and 51.85 per cent bromine. The formula  $C_6H_{12}O_4Br_2$  requires 23.4 per cent carbon, 3.9 per cent hydrogen, and 51.9 per cent bromine.

1,6-Dibromo-1,6-dideoxy-D-mannitol, 'Myelobromol'<sup>®</sup> (DBM)

1,6-Dibromo-1,6-dideoxy-dulcitol (DBD)

In acute toxicity experiments the  $LD_{50}$  is 685 mg/kg for mice, intraperitoneal, 470 mg/kg for rats, intraperitoneal, whereas it is 1,400 mg/kg for rats and 200 mg/kg for rabbits when given perorally. (Because of its poor solubility in water, 1:2,500, the DBD was administered in solution prepared with 'Tween 80'.) A single dose of 10–30 mg/kg markedly inhibits growth of more sensitive tumours (Yoshida, Walker, Shay tumours). A pronounced inhibition of more resistant tumours was brought about by six to ten repeated doses of 100–200 mg/kg. The peroral equivalent of these doses was about twice as much

DBD. Both the individual doses and the total quantity administrable could be raised considerably by giving the dose every second or third day; the side-effects became much milder.

The administration of 200 mg/kg to normal rats resulted in a transient increase of about 30 per cent in the leucocyte count of the peripheral blood which lasted for 12 h, together with the appearance of some immature forms. By 24 h a distinct leucopenia had set in, and reached its maximum, 50 per cent, within 72–96 h. The leucopenia ceased within a fortnight. There was no change in the red blood cells, even after larger doses, while the platelets decreased in number slightly. Optimal treatment did not cause a loss of weight; there was some gain in weight. Post-mortem examination revealed that the spleen was of normal size, the duodenum free of any microscopic lesion, and the inner organs appeared normal. The larger dose of 400 mg resulted in a severe depression of bone marrow: at the time of greatest effect the myeloid elements disappeared almost completely, and the nuclei of megakaryocytes showed lytic and pyknotic changes. Regeneration of myeloid elements commenced 120–144 h after damage. A fairly extensive destruction of white blood cells began in the spleen and lymph nodes after 3–6 h. There was also a large number of disintegrating cells, with

§ 75 per cent, with 25 per cent average life span of 28 days (controls 11 days).

pycnotic nuclei, in the duodenum. This effect, however, regressed within 48–72 h and after a further 1 or 2 days the tissue damage seemed to be repaired. In the parenchymatous organs histological investigation showed no damage. Data concerning the effects of DBD on tumour inhibition are given in Table 1.

With the Guérin tumour large doses of DBD resulted in visible cytological alterations by 1–3 h. The chromatin substance showed, under the electron microscope, a rough bundle-like arrangement<sup>3</sup>. Pycnotic derangement soon resulted in necrosis of the tumour (within 72–96 h). By this time there were multinuclear giant cells scattered around the vessels and in the connective tissue at the periphery of the tumour. Mitoses were scarce and occasionally deformed, even in the early stage. Yoshida ascites cells were enlarged in diameter to multiple size. *NK/Ly* ascitic lymphoma cells also showed less enlargement<sup>4</sup>. The same changes also occurred in tissue cultures of HeLa cells, especially with chronic treatment. The nuclei and nucleoli appeared puffy<sup>5</sup>.

The biological and tumour inhibiting properties of DBD differ from those of any other drug which we have so far tested: its cytological effects are obvious very soon and last for a long time, especially in tumours, and it therefore seems advisable to have long intervals between doses. DBD has a wide therapeutic range. The effect on the lymphoid organs and the duodenum fades much sooner than that on the myeloid elements and tumours. Relatively large doses are tolerated when given perorally and the effect seems even greater than that following intraperitoneal administration.

DBD in therapeutic doses provokes leucopenia and minor organic lesions of short duration. Of the cytological findings, cellular, nuclear and nucleolar enlargement is noteworthy, together with the early and long lived reduction of mitosis and a few deformed mitoses.

### Effect of Histones, Other Basic Proteins and Some Antibiotics on the Transplantability of Mouse Mammary Tumours

UNFRACTIONATED preparations of histones from normal mammalian tissues have been reported to inhibit the growth of transplantable tumours in rats<sup>1</sup>. Incubation of mucous cancer cells of liver with rat liver histone resulted in the inhibition of the growth of tumour by as much as 95.5 per cent. No cell or species specificity was found and there was a similar inhibition with rat thymus or calf thymus histones. Histones have been reported to play an important part in the regulation of RNA synthesis through the inhibition of the DNA-dependent RNA polymerase<sup>2,3</sup>. The ability to suppress DNA-primed RNA synthesis varies with different fractions of histones. Interest, therefore, now centres on histone fractions rather than on whole histone as regulators of gene action. We have examined the effects of whole histone, its two chief fractions and other chemicals on the growth of transplantable mouse mammary tumours.

Histone was prepared from calf thymus according to the method of Laurence *et al.*<sup>4</sup>. The fractions rich in lysine and arginine were isolated according to the methods of Johns *et al.*<sup>5</sup> and Johns and Butler<sup>6</sup>. The lysine-rich fraction was extracted in 5 per cent perchloric acid.

Mouse mammary tumour was induced in Swiss albino mice and maintained in our laboratory. Solid tumours were passed through a tissue press. The material was then suspended in Hanks solution and forced several times through a 20 gauge needle in a 20 ml. syringe into a sterile serum bottle. It was thus possible to obtain a satisfactory homogeneous cell suspension. The chemicals were dissolved in Hanks solution and the pH was adjusted to 7. They were mixed with the cell suspension, in an appropriate concentration and incubated for 2 h at 37°C. A sample (0.1 ml.) of this suspension containing approximately  $2 \times 10^6$  cells was injected into the left hind leg of a mouse. Tumours of 10–12 days growth were collected and weighed. A total of more than 400 Swiss albino mice of 5–7 weeks of age were used in these experiments.

The results of the effects of the basic proteins and other chemicals on the growth of the transplantable tumours are shown in Table 1. It was noticed that the lysine-rich histone, when used in a concentration greater than 5 mg/ml., inhibited tumour growth significantly. For example, at a concentration of 10 mg/ml. it showed 69 per cent inhibition. Whole histone or the arginine-rich fraction produced little or no inhibition. Unfractionated histone at a concentration of 7 mg/ml. showed 34–35 per cent stimulation in tumour growth. Spermine in a concentration of 10 mg/ml. resulted in 35–36 per cent inhibition while protamine and spermidine were ineffective. Polylysine when used in concentrations greater than 7 mg/ml. completely blocked the growth of transplanting tumours. Actinomycin had some effect, as 25 µg/ml. resulted in 59 per cent inhibition, but puromycin showed only 20–21 per cent inhibition at a concentration of 100 µg/ml.

In contrast with earlier observations<sup>1</sup> we found that unfractionated histone had no inhibitory effect on the growth of tumour. On the other hand, some stimulatory effect was observed with total histone (Table 1). Only the lysine-rich fraction reduced growth significantly. It

is likely that inhibition of growth of transplanted tumours in this case is due to the ability of lysine-rich fraction to repress the synthesis of DNA-primed RNA synthesis. This is supported by the fact that actinomycin-*D* and polylysine, well known suppressors of RNA synthesis, were also found to inhibit tumour growth. Our results are consistent with the report that the lysine-rich fraction of histone is most effective in repressing RNA synthesis while other fractions do so to a lesser degree<sup>2</sup>. Our results, however, are at variance with those which suggest that the arginine-rich fraction is a more effective inhibitor of RNA synthesis than the lysine-rich fraction in isolated calf thymus nuclei<sup>3</sup>. We also found that polylysine at concentrations more than 7 mg/ml. totally blocked the growth of transplanted tumours while protamine was not effective even at a concentration of 20 mg/ml. It is still difficult to suggest a mechanism for the striking difference between the effect of the lysine-rich fraction on the one hand, and the arginine-rich fraction and total histone on the other, in repression of tumour growth. It could be caused, as was already suggested<sup>2</sup>, by conformation variations of DNA-histone complexes which result from different fractions.

We thank Dr. W. L. Hughes, Tufts University School of Medicine, Boston, and Professor B. R. Seshachar of the Department of Zoology, University of Delhi, for help. Dr. Richard Egan supplied some samples of whole histone, and arginine-rich and lysine-rich fractions, and Dr. C. A. Stone gave the actinomycin-*D*.

### Quantitative Determination of Conjugated Bile Acids in Serum in Acute Hepatitis

LITTLE information is available about the variation in concentration of bile acid in serum in health and disease. This is mainly a result of methodological difficulties which result from the solubility of bile acids which closely resembles that of other lipids. Serum extracts prepared according to previous techniques often contain small quantities of lipid material which cause errors in the assay of bile acids<sup>1</sup>. Attempts to separate these interfering substances are often associated with considerable losses of bile acids. These difficulties explain discrepancies in values for the concentration of normal bile acid in serum which have been reported to range between 0 and 60 mg/ml.<sup>2</sup>

We therefore developed a method for quantitative determination of bile acids in serum which permits their assay in their biological forms of taurine and glycine conjugates<sup>3,4</sup>. After the extraction of serum with hot ethanol the bulk of lipids is removed by distribution in ether, ethanol, heptane and water. The conjugated bile acids are separated by thin layer chromatography as shown in Fig. 1. This procedure removes simultaneously bilirubin and the remaining lipids from the spots of bile acid. Reactions with sulphuric acid, salicylic aldehyde, sulphuric acid and acetic acid, and ethyl acetate, acetic acid anhydride and sulphuric acid, respectively, which are performed in the presence of the silica gel then permit the quantitative determination of the different conjugates.

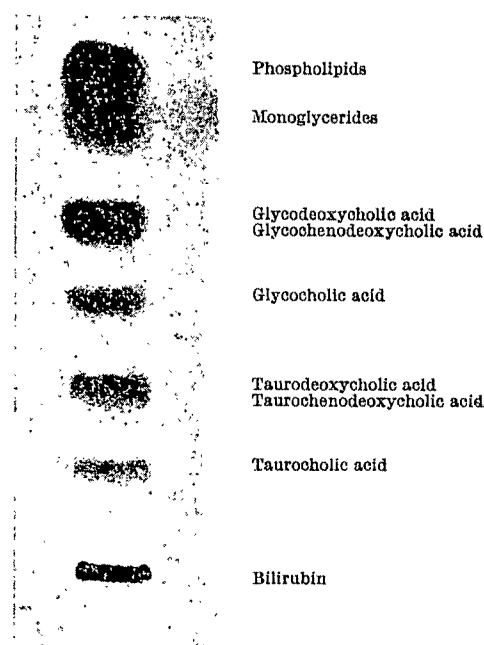

Fig. 1. Thin layer chromatographic separation of serum conjugated bile acids. Silica gel *G* provided the layer; butanol-acetic acid-water (10:1:1, v/v) was the solvent and 5 per cent ethanolic phosphomolybdic acid was the spray.

Fig. 2. Values of total and individual conjugated bile acids, bilirubin, and transaminases in serum during the course of acute hepatitis for patient K.R.E., aged 57. —, Total conjugated bile acids; ---, taurocholic acid; ····, taurochenodeoxycholic acid; - · - ·, glycocholic acid; - - - -, glycodeoxycholic acid.

Added pure conjugated bile acids were recovered to nearly 100 per cent. The sensitivity is 0.5 µg/ml. of serum. By this procedure serum from normal individuals contains no conjugated bile acids or only traces which cannot be measured.

Fig. 2 shows the alterations in serum conjugated bile acids in a case of acute hepatitis. There was an interval of 8 days between onset of icterus and the first determination of bile acids. Initially there was a considerable increase in most conjugates mainly caused by increased concentrations of taurochenodeoxycholic and glycochenodeoxycholic acids. The starting value of total conjugated bile acids was 330 µg/ml. of serum. During the period of observation in this patient with a clinically uncomplicated course of acute hepatitis the total conjugated bile acids decreased to 40 µg/ml. of serum. These alterations in concentrations of bile acid in serum were accompanied by similar deviations of concentration of bilirubin and enzyme in serum. Although the latter parameters were normalized at the end of the period of observation, however, bile acids still showed increased values.

This observation could be confirmed in twenty-eight additional patients with acute hepatitis, and in some cases increased concentrations of bile acid in serum on the one hand, and normal bilirubin and enzyme values on the other hand, persisted over several months. Concentrations of total serum conjugated bile acid after normalization of bilirubin and transaminases were 12–130 µg/ml. of serum. Liver biopsy specimens of such cases still showed histological abnormalities.

It is therefore concluded that determinations of conjugated bile acids in serum in the course of liver diseases are superior to other tests in the demonstration of abnormal liver cell function.

## BIOCHEMISTRY

### Multiple Specificity of Thrombin for Synthetic Substrates

THE original work on the activity of thrombin on synthetic substrates<sup>1</sup> indicated that its hydrolytic action was confined to the arginine esters and amides, but more recent investigations<sup>2</sup> have shown that the specificity of thrombin is very similar to that of trypsin, which hydrolyses both arginine and lysine esters. We have recently reported that thrombin also hydrolyses phenylalanine and tyrosine ester substrates (unpublished results), and we have therefore investigated the enzyme activity of thrombin towards a variety of amino-acid esters, to define more precisely the specificity of the enzyme.

Thrombin was obtained by activation of purified bovine prothrombin in 25 per cent sodium citrate, followed by purification of thrombin and removal of autoprothrombin C by chromatography on DEAE-cellulose columns<sup>3</sup>. The thrombin peak was concentrated as described<sup>4</sup>, dissolved in a 50 per cent solution of glycerol and saline, and the fibrinogen clotting activity was measured<sup>4</sup>. Amino-acid esters were obtained commercially as the hydrochlorides, dissolved in distilled water, and the pH was adjusted to 7.6 before it was made up to volume. The assay mixture consisted of 1 ml. of 0.2 molar *tris* hydrochloric acid buffer, pH 7.6; 0.2 ml. of 0.2 molar substrate; 0–0.2 ml. of thrombin; and 0.9 per cent saline to adjust the volume

to 2.0 ml. Hydrolysis was followed by a modification of the Hestrin technique<sup>5</sup>. Incubation was at 37° C. Control assays were run in the absence of enzyme to measure non-enzyme hydrolysis, and the values were subtracted from those obtained in tubes containing the enzyme.

Table 1 shows the results of the action of a thrombin preparation on a number of amino-acid esters. The results indicate that the specificity of thrombin is not as restricted as formerly believed. Not only are phenylalanine and tyrosine esters hydrolysed, but also tryptophan ethyl ester. These esters are typical chymotrypsin substrates. Their rate of hydrolysis, however, is quite slow compared with that at which substituted arginine and lysine esters are hydrolysed. Methionine ester, which can supply to some degree the necessary structural element for chymotrypsin catalysis, was not hydrolysed by thrombin. Histidine methyl ester is of intermediate activity as a thrombin substrate, and we have found that not only thrombin, but also trypsin and  $\alpha$ -chymotrypsin, catalyse the hydrolysis of histidine methyl ester. With crystalline preparations of trypsin and  $\alpha$ -chymotrypsin, approximately 38 µg of trypsin and 140 µg of chymotrypsin/ml. will catalyse 40 per cent of hydrolysis of histidine methyl ester in 1 h at 37° C at a substrate concentration of 0.02 molar, but 25 µg of thrombin are required. When thrombin is boiled its ability to catalyse the hydrolysis of histidine methyl ester is destroyed, and there is no measurable hydrolysis when 1 mg/ml. of crystalline serum albumin replaces thrombin in the assay mixture.

Current theory holds that the interaction of thrombin (and trypsin) with substrates containing arginine or lysine is facilitated by a positive charge on the guanido- or  $\epsilon$ -amino group of arginine and lysine, respectively, and so it is not surprising that those esters in Table 1 which meet these requirements are the most sensitive to thrombin catalysis. Histidine methyl ester would also belong to this category of positively charged amino-acid substrates, although the number of charged species would be lower at pH 7.6 than with arginine or lysine, because of the lower  $pK_a$  of the ionizable hydrogen of the imidazole group of histidine. It was recently demonstrated that a binding site for aromatic compounds exists at the active site of trypsin<sup>6</sup>, so that thrombin may also possess this capacity for binding aromatic compounds. This could explain how tyrosine, phenylalanine and tryptophan esters show some sensitivity to thrombin catalysis. The other esters in Table 1 apparently do not fulfil either a charge or structural requirement for binding to the active site of thrombin.

It is obvious from the data in Table 1 that substitution on the  $\alpha$ -amino group greatly increases the susceptibility of amino-acid esters to thrombin catalysis. The most

Table 1. HYDROLYTIC ACTIVITY OF BOVINE THROMBIN ON SYNTHETIC SUBSTRATES

Substrate*	Clotting (u/ml.)†	Percentage of hydrolysis (60 min)
Tosyl-lysine methyl ester	3	43
Tosyl-arginine methyl ester	3	41
Benzoyl-arginine methyl ester	3	22
Benzoyl-arginine ethyl ester	3	22
Arginine methyl ester	45	37

Histidine methyl ester	120	45 (29)‡
Lysine methyl ester	150	38
Tryptophan ethyl ester	650	21
Tyrosine ethyl ester	650	18
Phenylalanine methyl ester	650	16
Methionine methyl ester	650	0
Proline methyl ester	650	0
Serine methyl ester	650	0
Aspartic acid $\beta$ -methyl ester	650	0
Cysteine ethyl ester	650	0
Glycine methyl ester	650	0
Leucine ethyl ester	650	0

\* All substrates were tested at a final concentration of 0.02 molar. Except for DL-methionine methyl ester, the substrates were L isomer compounds.

† Clotting u/ml. refers to the amount of thrombin used/ml. of assay media. One clotting unit is that amount of thrombin which converts fibrinogen to fibrin in 15 sec under certain specified conditions<sup>4</sup>.

‡ Figures in parentheses indicate percentage of hydrolysis in 60 min where the concentration of ethanol in the assay system was 10 per cent.

notable example is the effect of the introduction of a *p*-toluenesulphonyl group on the  $\alpha$ -amino group of lysine, which increases the susceptibility to hydrolysis by about a factor of fifty, in these conditions of assay. Benzoyl-L-histidine methyl ester is also more susceptible to hydrolysis than histidine methyl ester, but because of the insolubility of benzoyl-L-histidine methyl ester in completely aqueous solutions, comparisons had to be made in a medium containing 10 per cent ethanol.

Certain amino-acid esters inhibit aggregation which is induced by adenosine diphosphate in blood platelets in an apparently competitive manner<sup>7</sup>. There is striking qualitative and quantitative similarity between those amino-acid esters which inhibited aggregation induced by ADP in platelets and the esters which we have found to be hydrolysed by thrombin preparations. The only exceptions are cysteine ethyl ester and aspartic acid- $\beta$ -methyl ester. The inhibition exhibited against ADP-induced aggregation of platelets by cysteine ester is probably due to its free sulphhydryl group rather than its ester linkage, since cysteine also inhibited, and inhibitory activity disappeared if the free sulphhydryl group was blocked. We have not detected hydrolysis of aspartic acid- $\beta$ -methyl ester by thrombin, while Salzman and Chambers found the ester to be of moderate activity as an inhibitor of ADP-induced platelet aggregation.

It is not yet known whether thrombin is the enzyme involved in the aggregation of platelets by ADP. It may be another enzyme similar in specificity to thrombin, but there is much evidence to indicate a relationship between prothrombin activation and degradation of ATP to ADP in haemostatic plug formation<sup>8</sup>, and others have shown that thrombin can liberate ADP from platelets<sup>9,10</sup>, resulting in platelet aggregation, although the mechanism by which this occurs is not known. There is similarity between the amino-acid esters which are hydrolysed by thrombin and those which inhibit ADP-induced aggregation of platelets, and so investigation of compounds which inhibit thrombin esterase activity might also indicate some which inhibit this aggregation as well. We have examined the inhibition of histidine methyl ester hydrolysis by thrombin, and our results are shown in Table 2. Both histamine and adenosine inhibit this reaction, although the effect of the latter is weak compared with those shown by phenethylamine, tyramine and tryptamine. Both histamine<sup>11</sup> and adenosine<sup>12</sup> have been reported as inhibitors of the ADP-induced aggregation of platelets. Agmatine and cadaverine, the decarboxylated derivatives of arginine and lysine, are also effective inhibitors of the hydrolysis of histidine methyl ester which is catalysed by thrombin.

The presence of carboxyl groups completely destroys the inhibitory action of the compounds as shown by comparison of the analogous compounds histamine and histidine. Reduction of the carboxyl group of histidine to histidinol changes it from an inactive to an active inhibitor. Another analogous pair of compounds are

$\epsilon$ -amino caproic acid and cadaverine. There is evidence that a primary amine is not necessary for inhibition in that choline and imidazole are inhibitory, although it has been reported that imidazole did not inhibit the aggregation of platelets in the same system that indicated histamine to be an inhibitor<sup>11</sup>.

Cross-reactivity of proteolytic enzymes to certain substrates is not unique in enzymology, as shown by the fact that  $\alpha$ -chymotrypsin can catalyse the hydrolysis of benzoyl arginine ethyl ester and trypsin can hydrolyse acetyl-L-tyrosine ethyl ester, although the rates at which these reactions occur are considerably lower than with the enzyme for which the substrate is usually considered to be specific. It is not surprising, therefore, that thrombin also demonstrates this cross-reactivity. Thrombin catalyses the hydrolysis of only arginyl-glycine bonds in fibrinogen, but in view of the several reactions in which thrombin is considered to play a part, such as activation of fibrin stabilizing factor, aggregation of blood platelets and release of contractile protein formation of prothrombin derivative and perhaps for the activation of prothrombin itself, thrombin may possibly exhibit multiple specificity depending on the presence of an inhibitor or accelerator and the availability of suitable hydrolysable bonds.

## Protein Synthesis and Enzyme Response to Contractile Activity in Skeletal Muscle

It was reported earlier<sup>1</sup> that increases in the specific creatine phosphokinase activity in the isolated frog sartorius muscle could be demonstrated in response to repeated isotonic contraction *in vitro*. A similar enzyme response has now been shown to take place when the frog sartorius muscle is made to contract isometrically once every 5 sec for 6 h at 18° C by stimuli of supramaximal intensity from a multi-electrode assembly of the type described by Hill<sup>2</sup>. It is of interest that under conditions in which the creatine phosphokinase activity increased by 30 per cent to 40 per cent, no significant increase in the ATPase of the whole homogenate could be demonstrated when it was measured in 2.5 mmolar ATP, 2.5 mmolar calcium chloride, 100 mmolar potassium chloride, and 100 mmolar *tris*-hydrochloric acid, pH 9.1. In these conditions of assay myosin is probably responsible for most of the ATPase activity, and so it can be concluded that the activity of this myofibrillar enzyme does not respond so readily to repeated contraction as do creatine phosphokinase and other sarcoplasmic enzymes. Preliminary experiments in which the frog sartorius was stimulated isometrically for up to 90 h at 2° C gave evidence of slight increases in the specific ATPase activity in the whole homogenate.

Table 2. INHIBITORS OF THE THROMBIN CATALYSED HYDROLYSIS OF HISTIDINE METHYL ESTER

	0.02 molar	Per cent inhibition* 0.04 molar	0.06 molar
Phenethylamine	42	48	60
Tyramine	33	64	70
Tryptamine	32	—	—
Agmatine	31	50	53
Cadaverine	17	25	38
Imidazole	10	16	—
Histamine	6	11	20
Choline	5	14	22
L-Histidinol	6	7	12
Adenosine	1	5	10

\* Inhibitor compounds were studied in the same assay system as that used for determining the specificity of thrombin toward amino-acid esters. The concentration of histidine methyl ester was 0.02 molar, and inhibition figures represent that after 60 min of incubation at 37° C, compared with the hydrolysis of histidine methyl ester by 120 U/ml. of thrombin in the absence of inhibitor. Inhibitors were adjusted to pH 7.6 before adding it to the assay system.

Related structures which are not inhibitors are  $\epsilon$ -amino caproic acid;  $\gamma$ -histidine; *N*-acetyl-L-histidine; imidazole acetic acid; urocanic acid; and  $\beta$ -phenyl propionic acid.

Table 1. EFFECT OF INHIBITORS OF PROTEIN SYNTHESIS ON THE INCREASE IN CREATINE PHOSPHOKINASE ACTIVITY INDUCED BY CONTINUED ISOMETRIC CONTRACTION IN THE ISOLATED FROG SARTORIUS MUSCLE

Inhibitor	Concentration	No. of muscle pairs	Mean creatine phosphokinase activities (mg of creatine/mg of nitrogen/min)			S.E. of difference	t	P
			Untreated stimulated	Treated stimulated	Difference			
Puromycin	200 mg/ml.	8	0.766	0.538	0.228	± 0.0122	18.73	< 0.001
p-Fluorophenyl alanine	10 mmolar	6	0.652	0.469	0.183	± 0.0079	23.2	< 0.001
Ethionine	20 mmolar	5	1.022	0.676	0.346	± 0.0136	25.4	< 0.001
Actinomycin D	20 µg/ml.	8	0.544	0.537	0.007	± 0.0123	0.833	< 0.44
8-Azaguanine	2 mmolar	6	0.800	0.591	0.209	± 0.0069	1.22	< 0.3
5-Bromouracil	2 mmolar	6	0.635	0.645	-0.010	± 0.0063	1.58	< 0.25

Creatine phosphokinase was assayed<sup>1</sup> on aliquots of whole homogenates of treated and untreated paired sartorius muscles after stimulation once every 5 sec for 6 h. Muscles were maintained at 18° C in oxygenated bicarbonate Ringer, pH 7.4 (ref. 4), containing 0.4 per cent (w/v) glucose. Variations in the concentrations of creatine phosphokinase in untreated unstimulated muscles in the different series are not significant as they are due to seasonal variations and differences in the batches of *Rana temporaria* used.

The time scale of the increase in creatine phosphokinase activity and the general nature of the adaptive response suggested that new enzyme had been synthesized as a result of the continued contractile activity. To test this hypothesis, the effects of various inhibitors of protein synthesis on the increase in the creatine phosphokinase activity observed after repeated isometric contraction were investigated. The summary of the results presented in Table 1 indicates that the amino-acid analogues ethionine and p-fluorophenylalanine, and the antibiotic puromycin, prevented the increase in creatine phosphokinase activity which was observed in stimulated but untreated control muscles. On the other hand, no significant effect on the increase in enzyme activity could be observed when the muscles were treated with actinomycin D, 5'-bromouracil and 8'-azaguanine. In all cases the tensions developed in the treated and untreated paired muscles were not significantly different as judged by the kymograph records. The heat produced<sup>2</sup> and presumably the metabolic activity were therefore similar in the two muscles. It was concluded that under those conditions in which creatine phosphokinase increases were inhibited, the effects could not be ascribed to impaired contractile or metabolic activity as a result of treatment by the inhibitor.

These results are compatible with the view that the increase in creatine phosphokinase observed in normal muscles is caused by the synthesis of new enzyme protein controlled by messenger RNA, which is stable during the 6 h experiment. It is possible, however, that the lack of effect obtained with the inhibitors of RNA synthesis is the result of their inability to penetrate the muscle cell membrane. In view of the experience of other investigators with these inhibitors in different systems and the results presented here with puromycin and amino-acid analogues, this explanation seems unlikely. Control experiments, in which the unstimulated frog sartorius muscles were treated with the inhibitors in otherwise identical conditions to those used during the experiments presented in Table 1, indicated that no significant changes in enzyme concentration were produced by the inhibitors *per se*.

Attempts have been made to demonstrate directly the synthesis of new protein in response to contractile activity by comparing the incorporation of leucine labelled with carbon-14 in the myofibrillar and the combined sarcoplasm and granular fractions of stimulated and resting sartorius muscles. After 1-2 h the level of incorporation of labelled leucine was similar in the myofibrillar and sarcoplasmic fractions, but after more prolonged periods of contractile activity, both fractions, and particularly the sarcoplasmic-granular fraction, contained significantly more counts in the stimulated muscle than in the resting control (Fig. 1). In view of the progress of incorporation with time it seems unlikely that these differences merely reflect a speeding up of the equilibration between the added leucine with the amino-acid pool and proteins in the stimulated muscle. The results illustrated in Fig. 1 suggest that complete equilibration is reached in both muscles within 2 h and that the increased rate of incorporation which is apparent in

prolonged stimulation is a consequence of an increase in protein synthesis which is induced by the repeated contractile activity.

It is possible that the increased creatine phosphokinase activity and the rise in incorporation of leucine which occur during continued contractile activity of the isolated frog sartorius may be related to changes in the non-collagen protein fraction which have been reported by Gutmann and collaborators<sup>6-8</sup> to accompany contractile activity *in vivo*. It is difficult, however, to relate the latter findings to our own, for after tetanic stimulation for some minutes increases in total protein continue for several hours<sup>6-8</sup>. Despite this difference in experimental design it could be significant that the effects observed were maximal 4-6 h after the start of the contractile activity in both cases.

Fig. 1. Comparison of the incorporation of labelled leucine in the total protein of the combined sarcoplasm and granular fraction of stimulated and resting frog sartorius muscles. ●, Stimulated muscle; ○, resting muscle. Paired frog sartorius muscles were maintained in Ringer as described in Table 1. In addition 2 µc. (0.01 µmole) of labelled leucine and 20 µmoles of valine were added to 12 ml. of Ringer solution. Right muscle was stimulated isometrically once every 5 sec for 6 h, and left muscle was unstimulated control. Muscles were immediately homogenized in 10 mmolar potassium chloride, and centrifuged for 15 min at 500 × g. Supernatant was precipitated with 15 per cent trichloroacetic acid and prepared for determination of protein bound radioactivity by a procedure similar to that of Manchester and Young<sup>4</sup>. Total nitrogen was determined by Nesslerization after conversion to ammonium sulphate.

We thank D. R. Wilkie and B. R. Jewell for advice on isometric stimulation and M. J. Kearsey for help in the statistical analysis. The work was supported by a research

expenses grant to S. V. P. from the Medical Research Council.

### A Stain for Sweat Pores

ALTHOUGH the hair follicle is clearly visible on simple inspection of the skin, the sweat pore remains hidden. In the course of chromatographic studies with *o*-phthalaldehyde, we have found a distinctive prolonged surface staining of the sweat pores of ourselves and our technicians<sup>1</sup>. As a result of subsequent study and observation a simple method was developed for selectively staining the sweat pore in light skinned individuals.

A 5 per cent solution of *o*-phthalaldehyde<sup>2</sup> in xylene was applied locally to the skin. Within 2–3 min black puncta appeared at each of the sweat gland orifices (Fig. 1). These stained pores remained in evidence until surface desquamation occurred 5–8 days later.

Fig. 1. Black puncta are sweat pores stained selectively by topical application of 5 per cent *o*-phthalaldehyde in xylene on human skin. Staining persists for several days.

Staining does not occur if sweating is completely absent. In the presence of gross sweating, diffuse staining of the stratum corneum develops. Thus optimal poral stains appear in association with low or minimal sweating rates. Although xylene is recommended as the vehicle for the *o*-phthalaldehyde, a variety of volatile anhydrous solvents can be used. Thus, ethyl ether is equally satisfactory. The concentration of *o*-phthalaldehyde may be varied from 1 to 10 per cent without greatly altering the stain. Highly purified *o*-phthalaldehyde has been found to be the most satisfactory of four grades.

Our investigation of the nature of this poral staining has suggested that the black non-fluorescent pigment results from the reaction of *o*-phthalaldehyde with a sweat constituent bound by the sweat pore.

Using paper chromatography, it was found that the addition of *o*-phthalaldehyde to a sweat droplet produced a black stain. Urine and saliva were similarly reactive. Testing known constituents of these secretions revealed that only ammonia produced a black colour in the presence of *o*-phthalaldehyde. It could be detected in dilutions of 1/50,000, a dilution appreciably greater than that found in sweat<sup>3,4</sup>. Further evidence that ammonia was responsible for the stain was furnished by the fact that ammonia shows the same electrophoretic mobility as the constituent in sweat, urine and saliva which is stained black by *o*-phthalaldehyde.

The specific poral staining observed seems to reflect the localizing effect of the sweat, as water is required for an ammonia-*o*-phthalaldehyde condensation to occur. It probably also reflects a greater concentration of ammonia in the keratin of the sweat pores.

This simple method of staining pores has been found useful as a site marker, as the black puncta persist even when the skin is washed. Furthermore, the puncta afford a means of measuring the rate of shedding of the poral horny layer. There seems to be no available method for bleaching or dissolving this black pigment, but 'Scotch' tape strippings or abrasive rubbing will remove it mechanically. Finally, this stain technique has been found useful in the study of disease. As an example, the healed plaques of psoriasis fail to show any staining, again demonstrating that no functional sweat pores exist in these areas.

### Bioassay of the Red Chromatophore Concentrating Hormone of the Crayfish

THE colour of many crustaceans changes in response to variations in the illumination and colour of their surroundings. These changes are brought about by the movement of pigment granules within special epidermal cells or chromatophores, and are controlled by substances liberated by neuro-secretory cells<sup>1–3</sup>. So far, however, no substance or substances responsible for the movement has been isolated in a pure form, although the preparation of extracts of enhanced activity has been reported by many authors<sup>4,5</sup>.

Crustacean eyestalks, generally considered to be rich in red concentrating hormone, have been used as a source of these extracts. We have found, however, that the activity, in units per weight of tissue, of the eyestalks of the sea water crayfish, *Jasus lalandei*, is not more than twice the activity of the ventral thorax, consisting of the thoracic exoskeleton, the legs, gills and the thoracic nervous cords. This portion of the animal, available commercially in a frozen state, has been used as our source of extracts of red concentrating hormone.

In the fresh water crayfish, the highest concentrations of red concentrating hormone are in the circumoesophageal connectives and tritocerebral commissures, while the thoracic cords also show substantial activity<sup>6</sup>. This may also be the case in the sea water crayfish. The portion of the animal containing the tritocerebral nervous tissues, however, is not well preserved by freezing and thus large scale extractions so far have had to be limited to thoracic material.

To measure the red concentrating activity of eyestalk extracts Östlund and Fänge<sup>6</sup> introduced the "Leander unit". They defined this as the smallest amount of hormone that will cause a distinct blanching of eyestalkless specimens of *Leander adspersus* within 20 min. Such a unit is difficult to measure precisely. We have studied the effect of highly purified *Jasus* red concentrating hormone at various concentrations on the red chromatophores of several crustaceans in an attempt to formulate a better activity unit and to find a convenient test animal. To determine the degree of concentration, the chromatophores of the upper tail fan were examined microscopically ( $\times 80$ ). The chromatophores were examined using the scale of Hogben and Slome<sup>7</sup>, in which stage 1 corresponds to complete concentration and stage 5 to full dispersion of pigment. The response of Australian fresh water crayfish or yabbie, *Cherax destructor*, is shown in Fig. 1.

The chromatophore stage reached at 15 or 30 min could not be accurately correlated with the concentration of the extract, but the plot of the logarithm of the area between control and experimental curves against the logarithm of extract concentration is approximately a straight line (Fig. 2). As the chromatophore stage value of control animals, injected with saline, remains reasonably constant, the area or activity value ( $A$ ) may be calculated from the following expression

$$A = 20[nV_0 - (V_1 + V_2 + \dots V_n)]$$

where ( $V_0$ ) is the control stage value and ( $V_1, V_2, \dots V_n$ ) are the values measured at equal intervals of time ( $t$ ) in hours after injection of the test solution and ( $n$ ) the number of intervals of time required for the chromatophores of the test animals to return to the stage value of the controls. For most animals, accurate values for ( $A$ ) are obtained when ( $t$ ) is equal to 15 min.

The value of twenty was chosen so that the amount of hormone which will just effect complete concentration of the red pigment in 15–30 min (see lowest curve, Fig. 1) has an activity value of approximately 100. The correlation of the activity value with hormone concentration enables the concentration of the red concentrating hormone to be determined and expressed in arbitrary units/ml. of dissolved substance. A convenient unit is the amount of hormone dissolved in 20  $\mu$ l. of Van Harreveld's saline<sup>8</sup> which on injection into a specimen of *Cherax destructor* of approximately 5 cm body length and adapted to a dark background ( $V_0 = 4.5-5$ ) has an activity value of 100. As 0.1 of this *Cherax* unit with an activity of 40 produces distinct blanching, 0.1 *Cherax* units probably approximates to one Leander unit.

As *Cherax destructor*, common in Australia, is not universally available, Table 1 tabulates the effect of

Fig. 1. Effect of *Jasus* extract of various concentrations on red chromatophores of *Cherax destructor*. Units of *Jasus* extract per dose and activity values:  $\circ$ , 1.0, 115;  $\Delta$ , 0.1, 23;  $\square$ , 0.01, 8;  $\bullet$ , 0.001, 4;  $\diamond$ , control, 0.

standard *Jasus lalandei* extract of 4 *Cherax* units per 20  $\mu$ l., activity value 180, on some crustaceans available in the United States. In all cases normal intact animals were used for assays. Strong responses were produced in two other Reptantia. The crab, *Uca pugnator*, showed a response equal to that of *Cherax*. Only the red pigment concentrated, the black pigment not being affected. The crayfish, *Procamburus simulans*, responded even more strongly than did the other two animals. With *Procamburus* the slope of the log-log plot (Fig. 2) is a little steeper than that obtained for *Cherax*, but with *Uca* the slope is less and allowances for this will be necessary to convert activity values to *Cherax* units when these animals are used for assay work. When a crude extract of the excised circumoesophageal connectives and trito-

cerebral commissures of *Cherax* was tested in *Cherax* itself, a log-log plot with a much flatter gradient was obtained (Fig. 3). This suggests that the active factors of *Cherax* and *Jasus* may be different, or that the crude *Cherax* extract contains substances that inhibit the catabolism of the hormone.

Fig. 3. Comparison of effects of *Cherax* central nervous system extract and *Jasus* thorax extract on *Cherax* red chromatophores. O, *Cherax* into *Cherax*; Δ, *Jasus* into *Cherax*.

In all Natantia (shrimp and prawns) tested, the response was considerably less than that of animals classified as Reptantia. This suggests a distinct difference in chromatophore control between the two sub-orders of the Decapoda. Also, both the black and red pigments of the Natantia tested responded to the *Jasus* extract.

The hormone is present in the source material in extremely small amounts and is unstable, especially in alkaline solution. Large amounts of tissue must therefore be extracted to obtain workable quantities of extract of high activity. In a series of purification steps which commence with the alcoholic extraction of about 1,000 lb. of crayfish and use countercurrent distributions, partition chromatography, and chromatography on 'Sephadex G-25', we have obtained a 5 mg fraction with an activity of 50,000 *Cherax* units per mg, or 0.02 μg = 1 unit. Although only 0.002 μg of this material is required to produce a distinct colour change, thin layer chromatography shows that it is still a mixture of several components. Work is in progress, starting with larger quantities of extract to isolate the hormone in sufficient amount for further purification and structural investigation.

## Perfusion Fluid for the Scorpion, *Heterometrus fulvipes*

In his work on the cardiac physiology of the scorpion, *Palamnaeus bengalensis* C. Koch, Kanungo<sup>1,2</sup> used a saline solution containing 0.65 g sodium chloride, 0.03 g potassium chloride and 0.03 g calcium chloride in 100 ml. of distilled water and adjusted the pH of the saline to 6.3 with phosphate buffer, according to Maluf<sup>3</sup>. He also studied the effect of pH and temperature on the heart beat of the scorpion and he has shown that the heart remained active between pH 6.1 and 6.5 and the maximum rate of heart beat was observed at 42° C.

The saline prepared and used by Kanungo<sup>1,2</sup> was not, however, satisfactory for use with the scorpion, *Heterometrus fulvipes*. It was found that the constituents and the pH of the saline medium used by Kanungo<sup>1,2</sup> caused the heart to stop beating in this species and it was therefore essential to arrive at a more satisfactory formula.

I have investigated various inorganic and organic constituents of the blood of the scorpion, *Heterometrus fulvipes*<sup>4,5</sup>, and prepared a perfusion fluid on the basis of a biochemical analysis of scorpion blood. The formula for the perfusion fluid was arrived at by converting the concentration of the various constituents of the blood (in mmoles/l. or mg/100 ml.) into g ions/l. The average value of the pH of the blood of the scorpion *Heterometrus fulvipes* investigated is 7.316 ± 0.089 (ref. 5). The quantity and relative proportions of sodium, potassium, calcium, magnesium, chloride, sulphate and glucose present in the blood and also the pH of the blood were considered while making the formula.

Using this method, the perfusion fluid for the scorpion, *Heterometrus fulvipes*, contains 8.596 g sodium chloride, 0.144 g potassium sulphate, 0.532 g calcium chloride, 0.464 g magnesium chloride and 0.500 g glucose in 1 l. of redistilled water. 'AnalaR' grade salts, except glucose, were dissolved in 1 l. of redistilled water and the pH of this solution was adjusted to pH 7.3 by adding 10–15 ml. of pH 7.3 *tris* buffer. The solution was tested and finally adjusted to pH 7.3. This solution (without glucose) was kept in the cold and could be used for 15 days. Before using this perfusion fluid, suitable amounts of glucose were added to it<sup>6</sup>.

The perfusion fluid prepared in this way was found to be more satisfactory for the scorpion, *Heterometrus fulvipes*. The heart, both *in situ* and isolated, maintained a constant beat for considerable lengths of time (that is, for 10–12 h). The duration of activity of the heart was further enhanced by changing the perfusion fluid at intervals. The period of normal heart activity of the scorpion was quite satisfactorily maintained for about 24 h. Normal heart activity was found at pH 7.3, and this value agrees with the normal blood pH of the scorpion, *Heterometrus fulvipes*<sup>6</sup>.

This perfusion fluid is being used to study the effect of various factors on the heart beat of the scorpion, *Heterometrus fulvipes*.

I thank Professor Kandula Pampapathi Rao for his guidance. I also thank the University Grants Commission for a junior research fellowship.

### Amino-acid Composition of Ascitic Fluid and Blood Plasma from Mice bearing Ehrlich-Lettre Tumour

WHEN an *in vitro* incubation system for amino-acid incorporation and protein synthesis by Ehrlich ascites tumour cells (unpublished results) was in development there was a need to find a natural environmental supply of amino-acids on which a synthetic medium could be based. For this reason the amino-acids of the ascitic fluid around the cells, the plasma of mice bearing ascitic tumour and the plasma of normal controls were analysed. The results give an added insight into the protein nutritional state of the tumour-bearing mouse.

Weanling male Webster Swiss white mice were fed on 'Purina' laboratory chow. Two days after arrival half of the mice were injected intraperitoneally with 0.1 ml. of the Ehrlich-Lettre strain of mouse ascites carcinoma. Seven days later both tumour-bearing and control groups were deprived of food for 4.5 h. Blood was then taken from the subclavian vein of each anaesthetized mouse with a heparinized Pasteur pipette and all the samples from each group were pooled in a heparinized 40 ml. centrifuge tube until 25 ml. of blood had been collected (thirty to forty mice). From this volume of blood 10 ml. of plasma could be obtained. The mice were decapitated, and a suspension of tumour was withdrawn from each animal and placed in separate 12 ml. centrifuge tubes containing heparin. In one experiment tumour was collected at room temperature during a period of 2.5 h. Haemorrhagic samples or those of insufficient quantity were discarded, and of the remaining seventeen samples 1.6 ml. portions of each were pooled in a 40 ml. centrifuge tube. To avoid any loss of amino-acids from the fluid for analysis as a result of cellular uptake during the long period of contact between cells and fluid, a second experiment was carried out with ascitic fluid obtained with the following precautions observed: tumour was collected into ice-cold tubes, centrifuged within 15 min at 0° C and the fluid was immediately decanted. From eighteen samples portions of 0.7 ml. were pooled to provide the 10 ml. of fluid required.

The plasma and ascitic fluid were prepared for quantitative analysis of the amino-acids essentially according to the instructions for preparation of blood samples given in the Beckman Instruction Manual. 'Dowex' 2 × 10 (200–400 mesh) was used for the column. Analysis for free amino-acids was performed in a Beckman Spinco automatic amino-acid analyser. The procedure for blood samples was also found satisfactory for tumour fluid samples.

The results of the analyses of amino-acids of mouse plasma are given in Table 1. The amino-acid composition of normal mouse plasma resembles that of human<sup>1</sup> and rat<sup>2</sup> plasma in general profile. Concentrations of amino-acids in plasma are in most cases lower in mouse than in the human or the rat, with the exception of lysine and arginine, which are higher in the mouse. In the plasma of tumour-bearing mice (compared with normal) there are decreased concentrations of practically all amino-acids. The decrease is particularly noticeable in concentrations of the essential amino-acids, whereas for the non-essentials most decreases are smaller, although aspartic and glutamic acids are even higher than normal.

Table 2 shows the amino-acid composition of ascitic fluid to be entirely different in profile from that of plasma. Many essential amino-acids are in even smaller concentrations than in the tumour-bearing plasma, with glycine, proline, glutamic and aspartic acids in particular greater than in normal plasma. On the other hand, glutamine plus asparagine is extremely low in ascitic fluid, which is of interest in view of the suggestion<sup>3</sup> that the stimulated incorporation of amino-acids into Ehrlich cells in the presence of ascitic fluid is largely a result of its content of glutamine. Incubation of cells in their fluid at room

temperature further increases the concentration of non-essential amino-acids in the fluid, especially alanine, glycine, proline, hydroxyproline and glutamic acid. Concentrations of essential amino-acids in the incubated sample are usually greater than those for ascitic fluid collected at 0° C. The relative constancy of the values for other substances measured in the analysis, apart from the amino-acids required for protein synthesis, contradicted any appreciable discrepancy between two different groups of source animals. It is, however, possible that the cells extrude amino-acids in addition to taking them up, and that this overshadows the preferential uptake (or retention) of essential amino-acids. In the presence of a greater total content of amino-acids, the balance between essential and non-essential amino-acids must be noted, that is, the increase in non-essentials is greater than the increase in essentials.

Table 1. COMPOSITION OF FREE AMINO-ACIDS AND OTHER NITROGENOUS SUBSTANCES IN PLASMA OF NORMAL AND TUMOUR-BEARING MICE

Ninhydrin reacting substance	Normal (μmoles/100 ml.)	Tumour-bearing (μmoles/100 ml.)
Arginine	16.8	4.52
Histidine	6.14	1.14
Isoleucine	6.68	0.98
Leucine	11.6	4.97
Lysine	39.5	23.2
Methionine	3.62	2.93
Phenylalanine	5.27	3.26
Threonine	9.91	6.66
Tryptophan	1.86	0.45
Valine	14.8	8.35
Total essential amino-acids	116.18	62.66
Alanine	38.9	20.4
Asparagine	49.4	41.9
Glutamine		
Aspartic acid	0.78	1.41
1/2 Cystine	4.55	1.50
Glycine	27.6	26.0
Glutamic acid	4.16	7.75
Hydroxyproline	4.13	3.11
Proline	8.74	8.56
Serine	11.5	3.35
Tyrosine	5.0	4.31
Total non-essential amino-acids	154.76	118.29
Total "protein" amino-acids	270.94	180.95
Ornithine	7.06	9.04
Ethanolamine	1.65	2.57
Ammonia	26.0	45.8
3-Methyl-histidine	0.27	0.80
Phosphoethanolamine	1.11	1.77
Taurine	52.4	49.4
Urea	772.0	686.0
Citrulline	7.57	5.18
α-Amino-n-butyric	0.45	0.72
Cystathionine	0.12	0.18

In interpreting the results, it appears on one hand that the tumour draws on its immediate environment, the ascitic fluid, for total amino-acids at a rate that taxes the ability of the tumour-bearing mouse to supply them by diffusion from the plasma. In turn, the plasma itself is deficient in its normal complement of amino-acids as a result of the presence of the tumour. On the other hand, the essential amino-acids are in particular demand, and the normal reaction of the body in such a situation, the breakdown of tissue protein, must take place to replenish the concentrations in the plasma. Since essential amino-acids are removed again at a greater rate than non-essentials, the plasma and in turn the ascitic fluid become more unbalanced. Swendseid *et al.* have used the molar ratio of essential to non-essential amino-acids (*E/N* ratio) in the plasma of humans<sup>4</sup> and rats<sup>5</sup> as an indication of protein nutritional status. An effect similar to the decrease in this ratio associated with insufficient protein diet and an attempt by the body to furnish essential amino-acids by breakdown of protein is observed in comparisons between normal mouse plasma (*E/N* ratio = 0.75), plasma of tumour-bearing mice (0.53) and ascitic fluid (0.36). Similarly, the contact of the ascitic fluid with cells *in vitro* suggests that the tumour cells also break down protein and replenish the medium so as to cause further imbalance of amino-acid composition (*E/N*

Table 2. COMPOSITION OF FREE AMINO-ACIDS AND OTHER NITROGENOUS SUBSTANCES IN ASCITIC FLUID OF EHRlich TUMOUR

Ninhydrin reacting substance	Fluid collected at 0° C (μmoles/100 ml.)	Fluid after being in contact with cells (μmoles/100 ml.)
Arginine	1.86	2.69
Histidine	5.03	7.22
Isoleucine	1.29	4.52
Leucine	2.07	7.49
Lysine	22.1	34.1
Methionine	1.89	3.05
Phenylalanine	2.57	5.60

Proline	3.71	3.23
Serine	2.84	4.61
Tyrosine		
Total non-essential amino-acids	155.47	331.64
Total "protein" amino-acids	210.80	424.41
Ornithine	4.07	7.10
Ethanolamine	1.50	4.25
Ammonia	33.7	77.2
3-Methyl-histidine	0.54	1.17
Phosphoethanolamine	6.41	8.47
Taurine	85.0	87.1
Urea	829.0	802.0
Citrulline	1.77	2.07
α-Amino-n-butyric	1.47	1.74
Cystathionine	0.12	0.18

ratio = 0.28 after incubation). An alternative explanation could be that loss of amino-acids to the medium causes the cells to lose essential ones to a lesser extent.

The stepwise depletion of concentrations of amino-acid both in plasma and further in ascitic fluid of tumour-bearing mice, and the similar increasing imbalance in the amino-acid "profile", are indicative of the great nutritional demands of the tumour on the plasma and the unsuccessful attempt of the host to replenish the amino-acids of the plasma. It is well known that the tumour grows by obtaining its amino-acids for protein synthesis not only from the diet but from breakdown of proteins in the normal tissues of the host<sup>6</sup>. The selective advantage given to tumours by their great capacity to take up and concentrate amino-acids from the blood, in view of the dynamic turnover of protein and subsequent release of its structural units to the blood, has been pointed out<sup>7</sup>. The data presented here fit in with the known syndrome whereby tumour gains protein at the expense of the host, and further elucidate the relationship between the tumour's uptake of amino-acids from the host and the host's stimulated breakdown of protein.

## Topochemical Approach in Studies of the Structure-Activity Relation: Enantio-enniatin B

THE interaction of a biologically active substance with a selective receptor (for instance, substrate and enzyme) to cause a certain physiological effect is chemically complex, requiring not only a certain minimum of steric congruity of the molecules but also a given electron density distribution in the interacting functional centres. If either of these requirements is not satisfied, the reaction will either not take place at all or its effectiveness will be diminished by several orders of magnitude. It is thus important to discover the limits of steric and electronic matching, both in the rational search for substances with similar, modified or antagonistic action, and to understand the underlying mechanism.

In order to define these limits it is not always necessary to use the usual technique of changing restricted areas of the molecule step by step. In the case of cyclic peptides and depsipeptides it is possible to change the whole molecule in such a way that the resultant analogues are still very similar to the parent compound, both in the overall spatial arrangements, that is topologically, and also with respect to the electronic nature of the functional groups. The topochemical approach to the structure-activity relation then becomes particularly fruitful.

We began to study the structure-activity problem from the topochemical standpoint with the enniatin antibiotics, in which the essential part played by steric factors (size of the depsipeptide ring, configuration of the hydroxy- and amino-acid residues, etc.) in biological activity had already been shown<sup>1</sup>. The antipode of enniatin B—enantio-enniatin B with the configurations of the amino- and hydroxy-acid residues opposite to those of enniatin B—was chosen as one of the first objects and was therefore synthesized.

Fig. 1.

Since enantio-enniatin B is the mirror image of the natural product, the stereoselective receptor should behave quite differently towards these two stereochemically non-equivalent molecules. One would not, therefore, have expected enantio-enniatin B to show biological activity; it would have been as groundless as looking for it in antipodes of such naturally occurring peptides as bradykinin<sup>2</sup>, angiotensin<sup>3</sup>, oxytocin<sup>4</sup>, etc., compounds that one may consider to be biologically inactive, provided, of course, no fundamentally different mechanism exists which could render them active (as, for instance, in the case of the *l* isomer of cycloserine<sup>5</sup>). We considered it very likely, however, that enantio-enniatin B would possess biological activity equal or close to that of enniatin B. Indeed, if one turns one of the formulas depicted in Fig. 1 by 60° in the plane of the figure, all the like asymmetric centres coincide, while each ester group will take the place of the *N*-methyl amide group and vice versa. Consequently, relative to the receptor there is only a structural difference between these two antipodes. At the same time the ester group models the amide group both spatially and in the electron density distribution. There should therefore be a close matching of both these topochemically similar antipodes to the same stereoselective receptor and they should possess similar activities. Another ground

Table 1. ANTIMICROBIAL ACTIVITY OF ENNIATIN B AND ENANTIO-ENNIATIN B

Compound	<i>Staph. aureus</i> 209 P	<i>Staph. aureus</i> UV-8	<i>Sarcina lutea</i>	<i>Bac. mycoides</i>	<i>Bac. subtilis</i>	<i>E. coli</i>	<i>Mycob. phlei</i>	<i>Mycob. tuberc.</i>	<i>Cand. albicans</i>	<i>Sacch. cerevisiae</i>	<i>Botrytis cinerea</i>	<i>Nigrospora oryzae</i>
Enniatin B	18	9	18	25-37	35-50	> 50	9-12	4-5-6	9-12	9-12	9	9
Enantio-enniatin B	18	9	18	25-37	35-50	> 50	9-12	4-5-6	9-12	9-12	9	9

for such an assumption was that in a number of cases<sup>6,7</sup> an exchange of amide and ester groups in naturally occurring peptides and depsipeptides without affecting their biological activity had been found.

We synthesized enantio-enniatin B by a scheme analogous to that for the total synthesis of enniatin B<sup>8</sup>. The product was found to be identical to the natural one in all physical and chemical properties except the optical properties (the rotatory dispersion curves were of the same shape but of opposite signs). A test of the antimicrobial behaviour of enantio-enniatin B showed it to possess exactly the same activity both qualitatively and quantitatively towards the organisms investigated as enniatin B (Table 1).

It is noteworthy that this is the first case when a naturally occurring compound and its antipode display absolutely the same biological properties along the entire range of the antimicrobial spectrum, which virtually excludes the possibility of a different mechanism of action.

Our discovery of the biological activity of enantio-enniatin B led to the conclusion that the mechanism of action of enniatin antibiotics depends on the correspondence of their entire molecules to the receptor, which according to the latest data<sup>9</sup> seems to belong to the group of mitochondrial lipoproteins, controlling the active cation transport in the mitochondria.

It should be mentioned that enniatin B and its antipode are an example in which two molecules are very similar, both topologically and in the character of the functional centres. If the latter is retained and the effective volume of the radicals in the depsipeptide molecule is changed, one may easily determine the limits of its topological correspondence to the receptor. At the same time, for a number of biologically active cyclopeptides one may obtain analogues which are identical topologically, but differ considerably from them in the nature or position of the atoms in the functional centres. The topochemical investigation of such analogues, which we are at present engaged in, might shed light not only on the nature of the interaction between the biologically active substance and receptor, but also on the structure of the receptor itself which is of particular importance in studies of enzyme systems. The authors are very grateful to Dr. I. D. Ryabova (Laboratory of Microbiology of our Institute) for carrying out the determination of the antimicrobial activity of enantio-enniatin B.

## Measurement of Gas Exchange in Woody Plants

METHODS of controlling Dutch elm disease have been investigated at this laboratory for the past four years. Emphasis has been placed on two approaches to the problem of control. One approach has been the search for a suitable chemotherapeutant to control the causal agent, the fungus *Ceratocystis ulmi* (Buism) C. Moreau. The other approach has been the screening of systemic insecticides to control its vectors, the European elm bark beetle, *Scolytus multistriatus* (Marsham), and the native elm bark beetle, *Hylurgopinus rufipes* (Eich). A difficulty was found in methods of measuring the effects of chemotherapeutants and pesticides on diseased and healthy American elms, *Ulmus americana* L., in the laboratory under controlled conditions. A careful survey of existing literature showed that no device existed for measuring the effects of chemotherapeutants, pesticides and disease. Indeed, other workers in these fields have expressed and emphasized the lack of methods of measuring disease in woody plants<sup>1,2</sup>. This led us to investigate respiration as a means of studying the effects of chemotherapeutants and pesticides on woody plants.

It has long been known that injured and diseased higher plants show an increase in respiratory rate<sup>3-5</sup>. Thus, it was assumed that if a diseased plant shows an increase in respiratory rate, then surely, once cured with a chemotherapeutant, it should respond with a decrease in its respiratory rate. Further, any injurious pesticide applied to a healthy plant should cause an increase in respiratory rate. With these assumptions in mind, a preliminary experiment was carried out with a simple device for measuring carbon dioxide, to determine whether the apparatus could readily distinguish healthy, injured and infected branch sections of woody plants.

References to diseased material in what follows are in all cases to branch sections of American elm, *Ulmus americana* L., infected with the Dutch elm disease fungus *Ceratocystis ulmi* (Buism) C. Moreau.

Various methods have been suggested and elaborate equipment constructed for observing gas exchange in plants<sup>6-8</sup>. But none is so simple and inexpensive to set up as the Pettenkoffer method<sup>9</sup>.

The apparatus used in our experiments consisted of twelve gas washing bottles and solenoid valves, an absorption tower, a respiration chamber, a multiple timer and a suction pump. The twelve gas washing bottles and solenoid valves were connected in parallel and then connected in series with the absorption tower, respiration chamber and suction pump. The entire apparatus was operated in total darkness in a growth chamber set at a temperature of 72° F.

Air was passed through an absorption tower containing a strong alkaline solution to remove the carbon dioxide. The air then entered the respiration chamber and, by means of solenoid valves activated by a multiple timer, each washing bottle was in turn switched into the air stream for 2 h. Each gas washing bottle contained 50 c.c. of 0.1 normal sodium hydroxide solution.

Titration was usually carried out after the end of a 24 h run. A 10 c.c. sample was pipetted from each gas bottle and 2 c.c. of a saturated solution of barium chloride was added to the sample to precipitate the carbonates. The solution was then titrated to the phenolphthalein end point.

Live branches of American elm were cut into 15 cm sections and the ends immediately sealed with paraffin.

The sealed branch sections were then sorted into three sets of samples, each set consisting of approximately 625 cm<sup>2</sup> of bark surface.

In each experiment the first sample set was a control. All branch sections in the second sample set were wounded with a girdling cut. The branch sections of the third sample set were wounded with a girdling cut and also inoculated with mycelium taken from a pure malt agar culture of *C. ulmi*. All branch sample sets were "conditioned" in respiration chambers in which air free from carbon dioxide was circulated for 48 h before the experiment. A 24 h run was made of each of the three sample sets before and after treatment as already described. All three sets were then maintained in respiration chambers into which a stream of air free from carbon dioxide was passed continuously. Periodically, during the next 14 days, the respiration level was determined for all three sets. The results for the first 72 h are plotted in Fig. 1.

Fig. 1. Relative respiration levels for control (...△...), injured (---●---) and inoculated (—○—) branch section for a 72 h period. Time of treatment is shown by an arrow. The recorded differences could be observed for periods up to 21 days.

It can readily be seen from the figure that the respiration rate for the first 24 h after "conditioning" for all three sets is approximately the same. After wounding however, the respiration rate increases sharply and then slowly falls to its previous level in about 8 h. In the wounded and inoculated set, the respiration rate increased sharply at first and then gradually increased to a maximum and maintained this level, indicating a diseased condition.

Branch sections which were wounded with a girdling cut only developed extensive wound tissue within 1 week. Those branch sections which were wounded and inoculated with mycelium of *C. ulmi* did not, however, develop any wound tissue, but exhibited the typical browning of the sapwood associated with vascular disease of elm.

The rate of respiration of the wounded and inoculated branch sections increased sharply at first and then gradually reached a maximum in approximately 8 h. The initial sharp rise in respiration was apparently caused by wounding, while the secondary increase was due to the presence of the fungus mycelium. It is difficult to believe that hyphae are able to penetrate the sapwood and cause such an extensive reaction in such a short time, and the reaction is therefore taken to indicate the presence of a toxin produced by the fungus. Other workers have shown that toxins are formed by *C. ulmi* in culture<sup>10,11</sup>.

This latter experiment was repeated several times, and a spread of 10.5–40.9 per cent in total respiration was found after inoculation of live branch sample sets from various elm trees. This is to be expected, as not all American elm show the same degree of susceptibility to the Dutch elm disease<sup>12</sup>. Elm branch sections from different trees should thus exhibit varying degrees of reaction when inoculated with *C. ulmi* mycelium.

The prolonged higher level of respiration of diseased branch sections can be thought of as due to prolonged injury. Just as the respiration rate in a wounded branch section returns to approximately its level before wounding, a diseased branch section can be expected to react with a lowering of respiration if the source of the prolonged injury is eliminated or reduced. Chemotherapeutants can therefore be screened in the laboratory by gas-exchange measurements on treated diseased branch sections. Systemic pesticides can be tested in the laboratory for phytotoxicity to woody plants, using respiration changes as a measure of the degree of injury. This approach may eliminate the costly and extensive field tests with chemotherapeutants and pesticides which have not yet proved their value. It should be emphasized, however, that this method of screening chemotherapeutants and pesticides is only a preliminary test which can help to establish desirable concentrations. Positive results in the laboratory will need confirmation under field conditions.

This investigation was supported by grants from the National Research Council and the Canadian National Sportsmen Show Association.

## Artificial Diet for the Adult Froghopper

THE adult froghopper, *Aeneolamia varia saccharina* (Distant), has been reared in the insectary on pieces of sugar cane leaf<sup>1</sup>, but the use of an artificial diet for the culture of this insect has not been reported. During investigations of the site of feeding and nutrition of *A. varia saccharina* a chemically defined diet (Table 1) was developed, and on this the insect could be successfully reared.

For preparation of the diet the required amount of cholesterol was dissolved in 1.5 ml. of acetone, the solu-

tion was added to 300 ml. of distilled water and boiled to remove the solvent<sup>6</sup>. The suspension was then remade to the original volume and the required quantities of all the other nutrients were added. The mixture was swirled for 20 min with one drop of 'Tween 20'<sup>6</sup>, boiled for a further 5 min, and the pH was adjusted to neutrality with 0.8 normal potassium hydroxide. The prepared diet was stored in a refrigerator at 4°–6° C and used when required.

Pairs of newly emerged adult insects which were held in cylindrical glass cages 1.5 in. long and 1.2 in. in diameter were given the diet which was impregnated on circular pieces of Whatman No. 1 filter paper placed between two pieces of parafilm stretched over one end of the cage<sup>7</sup>. The diet was renewed, and observations on longevity and fecundity were made every 24 h.

Comparisons of data from twenty-seven adult pairs reared on pieces of sugar cane leaf and the artificial diet are summarized in Table 2. Data previously presented<sup>1</sup> on the longevity and fecundity of thirty-seven female insects collected in the field and reared on pieces of sugar cane leaf are also included for comparison.

## ANTHROPOLOGY

### Radiocarbon Dating of Bone

SELLSTEDT *et al.*<sup>1</sup> have described a method for the removal of inorganic carbonates from bone so that the residual collagen can be used as a source material for radiocarbon dating, and they conclude that this "offers the archaeologist an elegant and versatile tool which is likely to find wide application".

The statement is not in accord with previous work in this field of which the authors appear to be unaware, and which has indicated that the problem of dating bone protein is, in fact, much more complex than Sellstedt *et al.* would seem to imply. Thus, Münnich<sup>2</sup>, using a method similar to that of Sellstedt *et al.*, was led to the conclusion that the mere removal of inorganic carbonates from buried bone (and also antler) was not in itself sufficient to guarantee a reliable result, because the strongly absorbent nature of the protein in these materials causes it to absorb "younger" organic material from its surroundings, and this cannot be completely removed. Also, Olson and Broecker<sup>3</sup> have described a method for the removal of both carbonates and humic acids from bone and have compared the dates obtained from this treated bone with those obtained from contemporaneous charcoal from the same sites. They obtained good agreement in some cases but not in others<sup>4</sup>. Tamers and Pearson<sup>5</sup> have compared dates obtained from bones which have been digested in strong acid (that is hydrolysed bone protein free from carbonates) with those from associated charcoal

and have also found serious discrepancies in many cases. Finally, Berger and Libby<sup>6</sup> have shown that a simple extraction with alkali will remove a considerable amount of more "recent" humic contamination from bone collagen, but their results do not indicate whether this treatment removes completely all non-contemporaneous contamination derived from humic material or other sources.

These results clearly indicate, therefore, that no general conclusions can safely be drawn about the suitability of bone as a source material for radiocarbon dating. Until a completely satisfactory method is developed for the removal of all non-contemporaneous contamination from bone protein, we must continue to rely on the establishment of criteria by which it is possible to assess the reliability of bone as dating material in any particular situation; as, for example, by direct comparison with more "reliable" organic materials such as wood charcoal<sup>7,8</sup> or bone charcoal<sup>9</sup> from the same archaeological context or even by exploiting the non-homogeneity of bone itself to provide a test for contamination as has been done for antler<sup>10</sup>.

## BIOLOGY

### Party Game Model of Biological Replication

THE analogy between the party game of Michie and Longuet-Higgins<sup>1</sup> and the reproduction of *E. coli* may not be exact, but it can, I think, be taken a little further.

All biosynthetic reactions need a source of energy, and the processes of cell reproduction involve much biosynthesis. In the same way, the party game requires a source of energy, and this is provided by the guests, who therefore have a far from passive role. They are the immediate sources of energy without which the printed instructions (enzymes) could not cause the assembly of ink and paper (substrates) to produce new forms (cells).

Those forms (cells) which are not reproduced merely fail to utilize a potential source of energy (uncooperative guests).

The limit to the final population can be corrected in the analogy if the previous paragraph is taken into account. There appears to be no limit to the number of forms a guest may copy, and therefore they need not be saturated with forms. What will be saturated as the number of forms increases, however, is this capacity to reproduce new forms, so that the rate of production becomes constant. This is comparable with linear growth on a restricted energy source, for example, of photosynthetic bacteria in a constant light source. Reproduction, of

course, stops when substrate or energy is no longer available.

Alterations can be made to the statements in French (that is, DNA). If they were minor (for example, the omission in Form 1, direction (2) of "un" or "de") the information would still be intelligible. But omission of such words as "papier" or "vingt" would form a nonsense statement. This would correspond to non-lethal and lethal mutations of DNA, respectively.

The statements in English could be wrongly printed. If the errors were small (for example, in Form 1, instruction II, omission or modification of "you" or "a") they would still allow the instruction to be obeyed. Omission of words such as "form" or "copy" would, however, give rise to non-functional statements. This would correspond to the production of modified proteins or enzymes which may be either still functional but perhaps impaired, or completely non-functional.

There may thus be scope in the analogy for evolution.

### Palaeo-electron Microscopy of Mummified Tissue

THE histology of Egyptian mummified tissues was first described by Ruffer in 1911 (refs. 1 and 2). He was able to demonstrate by light microscopy that some tissues

were well preserved, when rehydrated and embedded in paraffin. Because some skin and muscle from a mummified hand of ancient Egyptian origin dating approximately 600 B.C. recently became available, it was of interest to extend this field to the ultrastructural level with electron microscopy.

The mummified material when unwrapped was dry and brittle, and easily disintegrated. Such material was rehydrated according to Ruffer's method. Small pieces of tissue 1–2 mm in length were suspended for 24 h from a platinum loop in small tubes containing Ruffer solution, consisting of a mixture of 30 ml. absolute alcohol, 50 ml. of distilled water and 20 ml. of a 5 per cent sodium carbonate solution. Following hydration, tissues tended to fragment and therefore had to be handled with great care.

After rehydration, small fragments of tissue were suspended in 0.1 molar phosphate buffer solution for 5 min, and then were fixed for 1 h in 1 per cent osmium tetroxide buffered with 0.1 molar phosphate buffer (pH 7.2). After dehydration in a graded series of ethanol solutions, the tissues were embedded in a mixture of 'Epon' and 'Araldite' (modification of Luft's method<sup>3</sup>). Sections were cut with a glass knife on a microtome and picked up on uncoated grids, stained with lead hydroxide according to the method of Karnovsky<sup>4</sup>, and examined in an electron microscope. Micrographs were taken at initial magnification of 1,400–32,000 and were enlarged photographically as required. Thin sections of plastic embedded tissue were stained with toluidine blue according to the method of Trump, Smuckler and Benditt<sup>5</sup>.

Fig. 1. Low power micrograph of mummified skin. B, Basal epidermal cell layer; D, dermis; E, epidermis; N, cell nucleus; C, cytoplasm; PC, pericellular space; PN, perinuclear space. (Lead hydroxide "stain".)

Fig. 2. Mummified dermal cell. CM, Cell membrane; NM, nuclear membrane; M, cytoplasmic organelle; V, vacuole. (Lead hydroxide "stain".)

Fig. 3. Three non-nucleated cells, possibly erythrocytes (R). (Lead hydroxide "stain".)

Fig. 4. Bundle of muscle fibres. MF, muscle fibres.

The distinct histological features of skin were seen in the embedded sections, stained with toluidine blue. Nucleated cells were most numerous at the epidermal and dermal junctions.

Fig. 1 is a low power micrograph of mummified skin at the epidermal and dermal junctions, with numerous cells mainly in the dermal area. The cells are markedly shrunk with large perinuclear and pericellular spaces. A number of cells with intracytoplasmic vacuoles can also be seen. Fig. 2 is a high power micrograph of a dermal cell with an intact nuclear and cytoplasmic membrane. The nuclear membrane contains some nuclear pores and in an occasional area is double. A membranous organelle, possibly a mitochondrion, is also seen in the cytoplasm, which in addition contains a number of vacuoles of unknown origin. Two of the surrounding cells have pronounced perinuclear spaces. Fig. 3 shows three distinct intact cells which contain homogenous cytoplasm with occasional granules and no nuclei. These cells were surrounded by nucleated cells with perinuclear spaces, and possibly represent red blood cells in a small dermal vessel. Fig. 4 is a section showing a bundle of voluntary muscle fibres from the hand.

It is a credit to the ancient Egyptians that their method of mummification has so well preserved their dead, even at the cellular level. The marked shrinkage of cells observed in the processed tissue may have resulted, in part, from the soaking for 70 days in a brine bath which was commonly used in the mummification process in 600 B.C. (ref. 5). The perinuclear and cytoplasmic spaces are almost certainly artefacts following the crude re-hydration process.

There has recently been an increased interest in the field of palaeopathology<sup>6</sup>, and with the introduction of electron microscopy the examination of mummified material can be extended to the ultrastructural level. The pathology of mummified and even fossilized material may thus be compared with recent pathological specimens, and in the process infectious agents, such as viruses, bacteria and parasites, may be demonstrated.

I thank Miss Needler, of the Royal Ontario Museum, Toronto, who supplied the mummified material, Professor A. C. Ritchie for his assistance in the preparation of this manuscript, and Dr. Miyai, Mr. G. Doornewaard, Mr. H. Layne and Mrs. J. Cotkovski for their technical assistance.

### Reflected Light Interference Microscopy of Living and Fixed Biological Surfaces

WHEN malignant and normal mammalian cells were grown directly on metal surfaces, a new technique was developed to photograph living cultures on opaque surfaces<sup>1</sup>.

We considered that modification of an existing technique<sup>2</sup> could be used to photograph biological surfaces other than those of mammalian cells. Linskens and Krner<sup>3</sup> described a method whereby plant surfaces such as

leaves could be examined by means of surface interference microscopy of plastic and gelatine replicas. They state that, because plant surfaces are generally dull and reflect little light, it is difficult to record their surfaces photographically without the use of replicas.

Direct reflected light interference microscopy of the surface of philodendron and sweet potato leaves, by the method described for mammalian cells, did not give satisfactory photographs. A modification of the technique, however, gave superior surface detail both with transparent and semitransparent biological material.

Leaves of various plants were placed loosely between the two coverslips of Rose chambers<sup>4</sup>; a sheet of aluminium foil or a silver mirror surface was inserted behind the specimen so as to permit the light rays to be reflected back by the shiny surface. The Rose chamber was then put together loosely, taking care not to squash the specimen. The leaves were photographed in colour or black-and-white by means of the Nomarski reflected light interference attachment to the Reichert inverted universal camera microscope MeF (refs. 4 and 5). As can be seen in the pictures (Figs. 1, 2 and 3) the contour of the leaf surfaces is readily visible.

Leaf surfaces resting on glass did not photograph satisfactorily. This suggested that the insertion of a mirror or a shiny metal surface behind other biological surfaces might enable us to photograph these directly by reflected light. We chose cell cultures fixed for 1 sec in 10 per cent formalin. Fig. 4 shows KB cells grown on a glass coverslip and photographed by this method.

Investigation of a variety of transparent and semi-transparent biological specimens shows that this technique

may be used for direct photography of many types of plant and animal surfaces. By placing a mirror behind a culture of animal or plant cells growing on a glass surface, this method can be used to record changes in the surface of these cells as they are exposed to changes in their environment.

### Effect of Water Stress on the Photochemical Activity of Chloroplasts

GROWTH and accumulation of dry matter in plants are dependent on the water status of the photosynthetic tissues<sup>1-3</sup>. Stomatal closure, resulting from the increased water stress in the leaf, is usually considered to be the main cause of reduced photosynthesis<sup>4,5</sup>. Stomatal closure is not, however, a satisfactory explanation for reduced photosynthesis, especially in those cases where it has been

shown that there is no direct relationship between the degree of stomatal opening and carbon dioxide fixation<sup>6,7</sup>. It was suggested that damage by desiccation is caused, at least partly, by structural changes in the cytoplasm<sup>8</sup> and changes in the hydration of chloroplasts<sup>9</sup>. Some evidence showing a good correlation between the degree of hydration of the tissue and its photosynthetic activity in leaves with fully opened stomata has been produced<sup>10</sup>. We have therefore investigated the effect of drought and dehydration on the photochemical activity of chloroplasts.

Leaves of Swiss chard (*Beta vulgaris*—Stiel Mangold—Grüner breitrippiger, Riesen—Mauser Zuerich) were used throughout the experiments. The plants were grown in the greenhouse. Only fully expanded, mature leaves were taken for the experiments. Chloroplasts were isolated in sucrose buffer solution (0.05 molar *tris*, 0.4 molar sucrose, 0.01 molar sodium chloride, pH 7.8) by sedimentation at 1,000 g in the cold. Chlorophyll was estimated according to Arnon<sup>11</sup> and protein according to Lowry *et al.*<sup>12</sup>. Cyclic photophosphorylation mediated by phenazine methosulphate (PMS), and the Hill reaction mediated by ferricyanide or dichlorophenol-indophenol (DPIP), were measured according to Avron<sup>13-15</sup>. Plants were dehydrated by cessation of irrigation until permanent wilting occurred. Sometimes detached leaves were partially dried over calcium chloride.

The photochemical activity of chloroplasts isolated from leaves with different water content was compared. To ensure that the results obtained were caused by photochemical activity of chloroplast and not by the activity of other organelles, such as oxidative phosphorylation of mitochondria, dark controls were run in all the experiments. These dark controls were always negative.

The water content of leaves partially dried in desiccators was measured and chloroplasts were isolated from them. The results for the photochemical activity from some representative experiments are summarized in Table 1. These experiments show clearly that the loss of water from leaves results in a considerable reduction in photophosphorylative and photoreductive activity of the chloroplasts. Severe dehydration (loss of 50 per cent of the water of the leaf) abolishes these activities almost completely.

Table 1. PHOTOCHEMICAL ACTIVITY OF CHLOROPLASTS ISOLATED FROM LEAVES WITH DIFFERENT WATER CONTENT

No. of experiment	Condition of leaves	Percentage water content in leaves	Cyclic photophosphorylation	Photoreduction Ferricyanide	DPIP
1	Turgid	88.6	984	426	119
	Flaccid	71.7	692	290	79.5
	Percentage reduction		29.6	32.0	33.0
2	Turgid	90.2	760	330	138.5
	Flaccid	34.8	158	47	27.5
	Percentage reduction		79.2	85.2	80.6

Results for photoreduction expressed as  $\mu$ moles of ferricyanide or DPIP reduced/mg of chlorophyll/h. Results for photophosphorylation expressed as  $\mu$ moles of ATP formed/mg of chlorophyll/h.

Is this reduction in photochemical activity of chloroplasts, induced by dehydration, a transient effect or is more permanent damage caused? The effect of repeated cycles of drought is of special interest in this respect, and the effect of several such cycles was therefore investigated.

Control plants were irrigated regularly, and wilting never occurred. The treated plants, however, were re-irrigated whenever permanent wilting had occurred. The amount of water given allowed the restoration of full turgidity for 1 day only. The treated plants were exposed to six cycles of drought. Restoration of turgidity in the wilted plants was complete within 12 h of irrigation. The colour of the leaves, however, was not as deep green as that of the control leaves. Chloroplasts were repeatedly isolated from leaves taken from the control plants and from treated plants at the end of the fifth and sixth cycles of drought and again after the wilted plants had been

Table 2. EFFECT OF SEVERAL CYCLES OF DROUGHT ON PHOTOCHEMICAL ACTIVITY OF CHLOROPLASTS

Treatment	Condition of leaves	Percentage water content in leaves	Photo-reduction Ferricyanide	Remarks
Control	Turgid	90.0	387	At the end of fifth cycle of drought
Treated	Flaccid	81.6	242	
	Percentage reduction		37.5	
Control	Turgid	90.0	514	At the end of sixth cycle of drought
Treated	Flaccid	75.8	273	
	Percentage reduction		47.0	
Control	Turgid	90.0	532	After restoration of turgor
Treated	Turgid	90.0	474	
	Percentage reduction		11.0	

Results are expressed as in Table 1.

irrigated and full turgidity was restored. Only photo-reduction was investigated in these experiments. The results are given in Table 2. These results show that the ability of photoreduction in chloroplasts is reduced when the leaves lose their turgor. On restoration of turgor most of the activity is also restored. In other experiments it was shown that photoreduction, on re-irrigation, is restored to a much higher degree than photophosphorylation.

In another experiment the correlation between water content in the soil and in leaf and the effect of water loss on photochemical activity and on the ratio of protein:chlorophyll were investigated. The results are given in Table 3.

Table 3. PHOTOCHEMICAL ACTIVITY OF CHLOROPLASTS AND RATIOS OF PROTEIN:CHLOROPHYLL AS AFFECTED BY PROGRESSIVE LOSS OF WATER FROM THE LEAVES

Treatment	Days after irrigation	Condition of leaves	Percentage water content in soil	Percentage water content in leaf	$\mu$ moles of ferricyanide reduced	Ratio of protein/chlorophyll
Control	0	Turgid	25.4	90.0	339	
Treated (before treatment begun)	0	Turgid	25.4	90.0	335	
Control	0	Turgid	25.4	90.3	320	
Treated	5	Incipient wilting	13.0	80.9	321	
Control	0	Turgid	25.0	90.6	422	2.0
Treated	10	Flaccid	12.4	80.6	264	2.5
Control	0	Turgid	25.4	91.3	466	2.25
Treated	15	Flaccid	10.3	78.4	292	2.23

Control plants were irrigated daily. Treated plants were irrigated at beginning of experiment only.

These results show that large changes in photochemical activity of chloroplasts occur after the soil has been at its wilting point for some time and the plant has been exposed to prolonged water stress (between 5 and 10 days after irrigation). A very slight change in water content of the leaves, at this stage, was accompanied by a large change in photochemical activity. There seems to be a critical point of hydration, below which the photochemical apparatus is damaged.

The more or less equal ratios of protein:chlorophyll in the control and treated plants suggest that it is not the destruction of chlorophyll which causes the damage. A possible cause may be structural changes occurring as a result of the loss of water.

A preliminary experiment was carried out to investigate this possibility. Strips of tissue from turgid and flaccid leaves were fixed in 2 per cent permanganate. They were dehydrated according to the usual procedure, embedded in 'Epon' and prepared for electron microscopy. The control tissue appeared to be completely normal, but the sections from the flaccid leaves showed clear distortion of all the intergranal lamellae.

No precautions were taken to fix the flaccid tissue at the water potential prevailing in the leaf itself. It is possible, therefore, that the distortion of the intergranal lamellae was due to instantaneous rehydration during fixation. It is too early yet to make any assumptions as to the nature of structural changes which take place on

partial dehydration. The different behaviour of the two leaves suggests that such changes do take place.

### Flavianic Acid as a Hatching Agent for *Heterodera cruciferae* Franklin and Other Cyst Nematodes

MANY efficient artificial hatching agents are known for the beet cyst nematode, *Heterodera schachtii* Schm.<sup>1-7</sup>, some for the potato cyst nematode, *H. rostochiensis* Woll.<sup>7-9</sup>, but few or none for other economically important *Heterodera* species<sup>7</sup>.

Flavianic acid (2,4-dinitro-1-naphthol-7-sulphonic acid) effectively hatched eggs of the cyst nematodes *H. cruciferae*, *H. glycines* Ichinohe, *H. schachtii*, *H. tabacum* Lownsbury & Lownsbury and *H. trifolii* Goffart. It was less effective with *H. goettingiana* Liebs. and failed to hatch eggs of *H. carotae* Jones and *H. rostochiensis*. Of these species, eggs of *H. goettingiana*<sup>10</sup> and *H. glycines*<sup>7,11,12</sup> do not hatch *in vitro* in any root diffusates so far tried. *H. goettingiana* eggs do, however, hatch in soil when pea roots are present<sup>10</sup>; the reason for their different response *in vitro* and in the soil is unknown.

Table 1 shows the hatching activity of flavianic acid and of three other synthetic hatching agents with eight *Heterodera* species. Except for *H. goettingiana* and *H. glycines*, where the hatch in the compound is given as a percentage of that in distilled water and is in italics<sup>7</sup>, activity is expressed as a hatch rating from the formula at the foot of Table 1 (ref. 4).

A 0.6-3 mmolar aqueous solution of flavianic acid hatched more eggs of *H. cruciferae*, *H. schachtii* and *H. trifolii* than the appropriate root diffusates, and as many eggs of *H. tabacum* as hatched in root diffusate. Pea root diffusate was used as the standard for *H. trifolii* because clover root diffusate does not hatch this species *in vitro*<sup>13</sup>. Egg-plant root diffusate was used for *H. tabacum*. Table 1 also shows that flavianic acid hatched many eggs of *H. glycines*.

All four compounds hatched eggs of *H. schachtii*, but other species responded to some and not to others. None was active with *H. carotae*. Although very similar in morphology and host range, *H. tabacum* and *H. rostochiensis* responded differently to the four compounds. Anhydrotetrone acid was the only one that hatched the eggs of both species. *H. rostochiensis* was also hatched by picrolonic acid<sup>9</sup> but not by picric acid or flavianic acid, whereas the reverse held for *H. tabacum*. These two species also responded differently to inorganic ions<sup>7</sup>.

Table 1. HATCHING ACTIVITY OF FOUR COMPOUNDS FOR EIGHT SPECIES OF *Heterodera*, EXPRESSED AS A HATCH RATING

<i>Heterodera</i> species	Flavianic acid		Compound		Picolonic acid		Pleric acid	
	Hatch rating	(mmoles/l.)	Hatch rating	(mmoles/l.)	Hatch rating	(mmoles/l.)	Hatch rating	(mmoles/l.)
<i>H. carotae</i> , carrot cyst nematode	2*	0.6	2	10	1	3	4	10
<i>H. cruciferae</i> , cabbage cyst nematode	158†	0.6	-38§	3	-77	3	-55	2
<i>H. glycines</i> , soybean cyst nematode	1,146†	3			446	3	-93	3
<i>H. goettingiana</i> , pea cyst nematode	331	0.6	204	0.6	116	3	116	3
<i>H. rostochiensis</i> , potato cyst nematode	-3	0.6	90	3	102	0.6	4	2
<i>H. schachtii</i> , beet cyst nematode	110	0.6	68	3	130	3	238	2
<i>H. tabacum</i> , tobacco cyst nematode	90	3	107	3	14	2	70	3
<i>H. trifolii</i> , clover cyst nematode	311	3	9	10	5	3	-36	3

Based on the total number of eggs hatched after 3 weeks from three batches of 100 cysts, except for *H. tabacum* where batches were of 50 cysts.

\* Ratings in roman type: calculated from formula  $\frac{H_r - H_w}{H_d - H_w} \times 100$

where  $H_r$  is the hatch in compound, and  $H_d$  and  $H_w$  are the hatches in root diffusate and water, respectively. A hatch rating of -11 to -100 is inhibitory -10 to 10 inactive (water = 0), 11 to 20 weakly active, 21 to 90 moderately active and > 90 very active (root diffusate = 100)\*.

† Rating in italics: hatch in compound expressed as a percentage of the hatch in water. A hatch rating of -11 to -100 is inhibitory, -10 to 150, inactive (water = 100), 151 to 250 weakly active, 251 to 500 moderately active and > 500 very active.

‡ Bold type: very active stimulation.

§ Negative sign: percentage inhibition compared with hatch in water\*.

Flavianic acid, like the other compounds in Table 1, has an acidic enolic group connected to a conjugated unsaturated system. It also has a sulphonic acid group, but simple sulphonic acids, for example, *p*-toluene sulphonic acid, were inactive or only slightly active with *H. schachtii* and *H. rostochiensis*. With these two species, chain length between terminal polarizable atoms seems an important determinant of hatching activity.

### Inhibition of the Action of Phytochrome by the Herbicide CIPC

CIPC, (Chlorpropham) isopropyl *N*-(3-chlorophenyl) carbamate, and its analogues are inhibitors of protein synthesis in excised segments of seedling plants<sup>1</sup>. Investigation suggested that this inhibition is actually exercised on the synthesis or release of messenger RNA (ref. 2, and in preparation by Mann, Cota, Robles, Moretti and Yung). Thus it was of interest to determine whether this particular inhibitor could prevent the effect of light in stimulating germination of Grand Rapids lettuce seeds.

This requirement for light is mediated by phytochrome. Considerable evidence indicates that phytochrome must be converted to the  $P_{fr}$  form (with an absorbance maximum at 735 mμ) for germination to occur<sup>3</sup>. We have administered CIPC to seeds imbibing in darkness, irradiated them with red light (forming  $P_{fr}$ ), and removed CIPC by washing while at the same time giving far-red in order to inactivate  $P_{fr}$ . If the first stable effector substance synthesized by  $P_{fr}$  is neither a messenger RNA nor a protein, then CIPC should merely inhibit the expression (that is, germination) of such an effector substance. The ability to remove CIPC (by leaching) and  $P_{fr}$  (by irradiation with far-red) at will permits us to distinguish between an inhibition by CIPC of synthesis of a  $P_{fr}$ -induced effector substance, as opposed to an inhibition of further expression of this hypothetical effector. Our results, however, indicate that CIPC blocks the synthesis of effector substance rather than its expression.

The data are given in Table 1. Dry seeds were first irradiated with far-red light in an effort to minimize the percentage of light-insensitive seeds. They were moistened with a little distilled water or with a 30 p.p.m. solution of CIPC, stored in darkness for 8 h at 25° C, and then given a 15 min exposure to 660 mμ illumination obtained by filtering a fluorescent tube. After an additional 20 h of storage in darkness the seeds were irradiated with far-red illumination, obtained by filtering the output of a 25 W incandescent lamp. In darkness, the seeds were washed into an aluminium tea strainer, rinsed with a large volume of distilled water, and transferred to a Petri dish containing moist filter paper. After an additional 3 days of incubation in complete darkness (obtained by the use of aluminium foil wrappings), the percentage germination was determined. Any radical protrusion was rated as germination. In our experiments obvious differences in the length of roots were apparent only after treatment with *para*-fluorophenylalanine.

In some cases, the addition of CIPC was delayed until after 3 h of imbibition. A considerably increased sensitivity to red light occurs during this period<sup>4</sup>. Delayed addition of CIPC, however, had no effect on our results.

Table 1. EFFECT OF CIPC OR PFPA ON STIMULATION BY RED LIGHT OF GERMINATION OF GRAND RAPIDS LETTUCE SEEDS

Light regime	Water	Percentage germination		
		CIPC at start	CIPC at 3 h	PFPA at start
Darkness*	31	30	—	0
Red at 8 h, far-red at 28 h	96	43	27	71
Red at 8 h, far-red and then red at 28 h	96	87	90	67

Concentration of CIPC was 30 p.p.m. All seeds were washed in complete darkness with distilled water after 28 h of imbibition, irradiated as described, and replated on moist filter paper. Phenylalanine (30 mg/l.) was added to seeds which had been treated with PFPA. One to two hundred seeds were used for each treatment. (Other details in text.)

\* Seeds kept in darkness were not washed free of inhibitors.

CIPC almost completely counteracted the effect of  $P_{fr}$  in stimulating germination, yet it did not affect the germination of the 30 per cent of light-independent seeds which germinated in the absence of red irradiation. CIPC did not cause any permanent injury to the seeds. If, after leaching and irradiation with far-red for 28 h, an additional dose of red light was given, the percentage germination increased to normal levels (Table 1). Similar findings with regard to the effect of anaerobiosis on the "escape phenomenon" have been reported<sup>5</sup>.

Experiments with other nominal inhibitors of protein synthesis (puromycin, azetidine-2-carboxylic acid, and *para*-fluorophenylalanine, PFPA) were carried out. Only PFPA penetrated the intact seed coat, as measured by inhibition of light-independent germination. PFPA did not block germination which was stimulated by  $P_{fr}$  other than with a slight generalized toxicity (Table 1).

We conclude that the first stable product of the action of  $P_{fr}$  is a specific messenger RNA. This explanation can

be generalized to other actions of phytochrome concerned with, for instance, flowering, and pigment synthesis, if it can be assumed that not only a "germination messenger" is under phytochrome control, but other messengers as well, according to the species and tissue in question. A similar hypothesis for the action of phytochrome has been suggested<sup>6</sup>, but it is not clear whether the high energy response in *Sinapis alba* is truly a phenomenon controlled by phytochrome.

This work was supported by a U.S. Public Health Service grant. We thank Dr. W. M. Dugger for the use of his darkroom.

### Fine Structure of the Dinoflagellate Transverse Flagellum

THE dinoflagellates have for some time been known to possess two flagella which differ from one another in their movements and in the orientation of the beating portions. One, called the posterior or longitudinal flagellum, has a relatively slow movement which has been shown to be in the form of a planar wave<sup>1,2</sup>. Electron microscopy shows that this flagellum is constructed of the normal axoneme plus organized packing material in the proximal two-thirds, all surrounded by a membrane. The transverse flagellum, often situated in a groove around the cell, has a completely different type of motion. With the light microscope it appears ribbon-like<sup>3</sup> and has a rapid undulatory motion which recent investigations have shown to be in the form of a circular or elliptical helical wave<sup>1</sup> (in *Ceratium*). In an early electron microscopical study of *Gyrodinium*<sup>4</sup>, it was found that this flagellum had an expanded sheath much wider than the axoneme, with an array of fine hairs along one side. Our observations have confirmed these findings and have revealed other structures which account for the unusual behaviour of this flagellum.

The transverse flagellum is a true flagellum, since it possesses the normal axoneme of 9+2 fibrils. These emerge from a basal structure identical to that of the longitudinal flagellum and only slightly different from that of other flagellates. When direct mounts are made (Fig. 1) the axoneme always shows a wave form which never completely straightens out, and it bears long fine hairs. Also present within the loose flagellar sheathing membrane is a banded structure—the striated strand (Figs. 2, 4 and 5) and organized packing material (Fig. 3) which occupies space not filled by the axoneme and the strand. The striated strand is composed of fibrous protein with banding showing an overall periodicity of 660 Å. This strand is much shorter than the axoneme and follows an almost straight path.

Because the short striated strand and the long axoneme are held together by packing material and flagellar sheath, the flagellum adopts a helical form rather like that of a drawn-out spiral staircase. A model constructed of tight string and wire in a sheath gives a similar result. Thus the structure of the flagellum dictates the form which its movement must take. The flagellum is held in position around the dinoflagellate cell by a relatively loose attachment of the tip in the region of the flagellar bases. There

Fig. 5. Drawing to explain Fig. 4. a, Axoneme; p, packing material; s, striated strand.

is no membranous connexion all round the girdle of the type which has often been postulated.

Electron microscopical observations have therefore revealed that the dinoflagellate transverse flagellum is one of the more complex types of flagellum known. In view of its specialized and unusual function this is perhaps not altogether surprising. Further details of the structure of dinoflagellate flagella will be published elsewhere.

### Production of New Physiologic Races in *Puccinia striiformis* (Yellow Rust) by Heterokaryosis

THERE is no known pycnial stage in *P. striiformis*, and so it is impossible for new physiologic races to arise as a result of sexual recombination, the best known method in *P. graminis*<sup>1</sup>. Nevertheless, there are at least thirty known races on wheat alone in Europe and Asia<sup>2</sup> and two new races, 2B and 8B, have appeared in Britain within the past 15 years<sup>3</sup>, and the epidemic in 1966 on the wheat variety Rothwell Perdix may well be caused by a further new race. Mutation and cytoplasmic change are possible causes of the production of new races, but it seemed to us that heterokaryosis<sup>4</sup> or parasexual phenomena<sup>5</sup> in the uredospore stage (both known in *P. graminis*) could be involved.

Experiments were carried out involving the mixture of uredospores of two physiologic races. A mixture of the uredospores of races 2B and 8B was inoculated on to seedlings of Strubes Dickkopf (a wheat susceptible to both races) and thirty single uredospore cultures were made from the resulting infection. When tested on the eleven standard differential wheat varieties<sup>6</sup> with the addition of Cappelle Desprez (distinguishing race 2B from race 2) and Heines VII (distinguishing race 8B from race 8), twenty-seven isolates resembled one or other parent, but the other three differed significantly from either (Table 1) in their reactions on four of the differential hosts. The reactions are given on the standard scale<sup>6</sup>, 0 being immune and IV highly susceptible. SSC 4 (and SSC 27, which closely resembled it) are less virulent than the parent races, but SSC 21 is more virulent, and could be of considerable importance if it became established in the field. Both races appear to be different from any previously described<sup>2</sup>.

Table 1. REACTIONS OF NEW PHYSIOLOGIC RACES AND THEIR PARENTS

Race	Vilmorin 23	Rouge prolifique barbu	Heines VII	Cappelle Desprez
2B	IV	II-IV	0	IV
8B	0-I	0-II	0-IV	0
SSC 4	I-II	0	0	IV
SSC 21	IV	II-IV	0-IV	IV

The production of these races can be explained on the basis of heterokaryosis: the parasexual cycle may be involved, but it is not necessary to invoke it to explain the results obtained, and the simplest explanation, that of simple reassortment of heterokaryotic nuclei, is preferred. Each uredospore possesses two nuclei, and if these were, after hyphal fusion, to change partners, two but not more than two new races would be expected if the parent races were heterokaryotic. The formation of hyphal fusions, and the passage of cell contents from one germ tube to another, have been observed by us, and will be described fully elsewhere.

The production of new physiologic races by hybridization in the uredospore stage provides a method for determining, in the absence of any sexual stage, the genetical factors responsible for virulence in the rust. The results reported here are insufficient to make more than a very preliminary determination, but they are in accordance with the postulate that three factors for virulence in the rust genome are involved. The action of the factor postulated as conferring virulence to Heines VII is very distinct. The factor conferring virulence to Vilmorin 23 is distinct from the one conferring virulence to Cappelle, since SSC 4 gives a type IV reaction on Cappelle, but only a type I-II reaction on Vilmorin 23, in contrast to the type IV reaction given by race 2B and SSC 21, the other two isolates attacking Cappelle. The difference between these two reaction types is accepted as being highly significant<sup>7</sup>. If the absence of parasexual phenomena is assumed, the factor conferring virulence to Cappelle must be inherited as a dominant character; the evidence is insufficient to determine whether the other two factors are recessive or dominant.

### Juvenile Sterility in Male Ticks of *Ornithodoros tholozani*

DURING an investigation of the physiology of reproduction in ticks, we observed that young male ticks of *Ornithodoros tholozani* are temporarily sterile, although they may copulate.

Young unfed males of *O. tholozani*, *O. lahorensis* and *O. tartakovskyi* generally copulate at 4-6 days old<sup>1</sup>, but they sometimes do so as soon as a few hours after ecdysis. To ascertain whether fertilization had taken place, the female was dissected after copulation and the uterus was inspected for the presence of a spermatophore. A spermatophore in the uterus was taken as an indication that fertilization had taken place. This conclusion should be modified, at least in the case of *O. tholozani*.

Our observations on the fertility of *O. tholozani* also showed that young unfed males are able to copulate. In our experiments some males began to copulate on the day after ecdysis and continued to do so at short intervals. Other males began to copulate later in their life. The presence of a spermatophore in the female's uterus does not, however, suffice to prove the ability of the male to fertilize a female.

Only microscopic examination of a spermatophore which has been dissected out of the uterus reveals the true contents of the spermatophore. The first spermatophores produced by a male generally do not contain sperm. They do, however, contain the sperm symbiotes *Adlerocystis ornithodori* which develop in one pair of the complex of accessory lobes of the male genital system which function as a mycetome<sup>2</sup> (Figs. 1 and 2).

Sterility is generally observed in young males of *O. tholozani* for 2 weeks after ecdysis. During this time a male may copulate up to five times, but all the spermatophores produced will contain no sperm. The entire process of copulation, as well as the spermatophore itself, is apparently normal, apart from the absence of sperm.

Fig. 1. A whole spermatophore of *Ornithodoros tholozani* before its introduction into the female ( $\times 20$ ). On light pressure on the cover glass the inner capsules, with all their contents, oozed out of the outer bulb. Note the large number of *Adlerocystis* forming "clouds" and the total absence of sperm cells. It was the first copulation of a male 24–48 h old.

Fig. 2. "Spermal fluid" of a spermatophore containing no sperm cells, but *Adlerocystis ornithodori* ( $\times 160$ ). The spermatophore was dissected out of the uterus 5 days after copulation. At copulation the male was 8 days old, and it was its second copulation.

One third (eight out of twenty-four) of the males in our experiments did not copulate before they became fertile.

The starved males usually start to produce sperm and become fertile at age 9–13 days. One male, however, produced sperm on the day after ecdysis, while another produced a spermatophore, which did not contain sperm at its first copulation, when it was 80 days old; the same male produced sperm at its second copulation, 13 days later. If the young male accepts a feed soon after ecdysis, sperm are found in its spermatophore about 5 days after the feed.

The presence of the spermatophore in the uterus is therefore no evidence of the ability of a male to fertilize, but only to copulate. So far as we know, this is the first observation of regular and normal sterility in young male individuals, who nevertheless copulate in an apparently normal way. We propose to call this phenomenon "juvenile sterility".

This investigation was supported by a research grant from the National Institutes of Health, U.S. Public Health Service.

## Attraction of *Apis mellifera* Drones by the Odours of the Queens of Two Other Species of Honeybees

ETHANOL extracts of the queens of three species of honeybees, *Apis mellifera*, *A. cerana* sub-species *indica* and *A. florea*, contain substances that inhibit both queen rearing by workers of *A. mellifera* and development of the ovaries of workers of this species<sup>1,2</sup>. Rearing of queens and development of workers' ovaries in *A. mellifera* colonies are inhibited by the pheromone, 9-oxodec-2-enoic acid, which is produced in the queen's mandibular glands<sup>3</sup> and which also serves as the olfactory sex attractant in this species<sup>4,5</sup>. It has been suggested that it would be interesting to find out whether the odours of the queens of the other three species of honeybees, *Apis cerana*, *A. dorsata* and *A. florea*, attract drones of *A. mellifera* and, if so, whether such attraction is also caused by 9-oxodecenoic acid<sup>2</sup>. Nubile virgin queens of these species were not available, and so tests were made with mated queens of *A. cerana* sub-species *indica* and *A. florea* which had been preserved in ethanol for several years.

The ethanol in which the *A. cerana* and *A. florea* queens had been stored was evaporated to a small volume on a water bath, poured over the respective queens and allowed to dry at room temperature. The two queens and an *A. mellifera* queen were hidden in separate wire gauze cages, each 1 cm  $\times$  2 cm  $\times$  8 cm, and exposed, one at a time on a warm afternoon when drones were flying freely, at the top of a tripod 6 m high. A dead *A. mellifera* worker in another wire gauze cage was used as a control. Using the technique devised by Butler and Faurey<sup>6</sup>, each cage was exposed in turn for 2 min and the drones which approached a dead worker bee suspended by a nylon thread about 1.2 m directly downwind of the cage were counted. Each cage was exposed ten times; results are shown in Table 1.

Table 1. ATTRACTION OF ODOURS OF MATED QUEENS OF *Apis cerana* SUB-SPECIES *indica*, *A. florea* AND *A. mellifera* TO FLYING DRONES OF *A. mellifera*

	<i>A. cerana</i> queen	<i>A. florea</i> queen	<i>A. mellifera</i> queen	<i>A. mellifera</i> worker
Mean No. of drone visits in 2 min	25.3	25.9	24.5	0.2
S.E. of mean	4.41	5.19	5.89	0.13

The mean number of drones attracted by the odours of the three species of *Apis* queens did not differ significantly, but did differ significantly from the number attracted by the *A. mellifera* worker used as a control ( $P < 0.001$ ), indicating that queens of *A. cerana* sub-species *indica* and of *A. florea* produce one or more volatile substances that attract *A. mellifera* drones.

When the attraction of the queens to *A. mellifera* drones had been established each was stored in ethanol and, later, examined chemically. The head of each queen was removed and extracted with ether. This extract was combined with the ethanol in which the queen had been kept, the whole evaporated to dryness and the residue was methylated<sup>6</sup>. The resulting pentane extracts containing methyl esters were evaporated and the residues dissolved in acetone. Care was taken to avoid any possibility of contamination during preparation and analysis of these extracts. Portions (usually 0.1 per cent) were analysed by gas chromatography using a Perkin-Elmer F11 chromatograph with dual 6 ft. columns of silicone gum rubber E-301 on 'Chromosorb W' at 152°C. A major peak was observed, in the chromatogram of material from each queen, which had the same retention time as methyl 9-oxo-dec-2-enoate and was not separated from this on co-chromatography. It is therefore inferred that the queens of both *A. cerana* and *A. florea* contained 9-oxodecenoic acid and this attracted the *A. mellifera* drones.

Because of the previous history of these queens, their original content of 9-oxodecenoic acid could not be accurately estimated, but the amounts detected were of

the order of 10 µg/queen, which can be taken as a minimum value.

Whether, given the right conditions, 9-oxodecenoic acid attracts drones of *A. cerana* and *A. florea*, and whether queens of the fourth species of honeybee, *A. dorsata*, also produce 9-oxodecenoic acid has still to be determined, but both seem probable. If it is found that 9-oxodecenoic acid forms the whole, or part, of the olfactory sex attractant of several species of *Apis*, the question arises how interspecific attraction is prevented in regions where two or more species co-exist. Interspecific matings are unlikely because of disparity in size and anatomical differences between the drones.

Most olfactory sex attractants may be species specific, but enough exceptions are known to show that such specificity is not essential to prevent indiscriminate cross-mating even between closely related species, for example, gypsy moth, *Porthetria dispar*, and nun moth, *Porthetria monacha*<sup>7</sup>, tobacco moth, *Ephestia elutella*, and Mediterranean flour moth, *Ephestia kuehniella*<sup>8</sup>.

### Larval Moulting Cycle and DNA Synthesis in *Drosophila hydei* Salivary Glands

IN *Drosophila*, cell division stops from the time the salivary gland primordium is formed in the embryo, and no mitoses have been observed in the glands after this stage. The number of the cells present remains the same throughout the entire larval development and the increase in size of the glands is merely due to cell growth<sup>1</sup>.

Histophotometric measurements of the DNA content per nucleus show that during the larval development DNA undergoes progressive duplication. On the basis of data by Swift and Rasch (see Alfert<sup>2</sup>), it seems that this process leads to an increase of total DNA content per cell up to 1,024 times the normal haploid value.

According to Plaut<sup>3</sup>, the number of duplications of original non-polytene DNA should be eight, and "... since it takes about 1 week under normal culturing conditions for eggs to develop into late third instar larvae, the average time for each of the eight replication cycles is about 20 hours". Plaut suggests also that the cells with polytene chromosomes of *Drosophila* salivary glands have a pattern of DNA synthesis similar to that of the other non-polytene cells; each synthetic activity should lead to a precise doubling of the pre-existing DNA and should be separated from the next period of synthesis by a pause in which there is no DNA synthesis.

Some authors<sup>4,5</sup> are in favour of the view that larval development, with the profound metabolic changes taking place at each moult, is a discontinuous process. Certain hormones, such as ecdysone, seem to play an important part in this connexion. There is some evidence suggesting that ecdysone may interfere with nucleic acid metabolism (see review by Wigglesworth<sup>6</sup> and the experiments on puffing patterns induced by injection of ecdysone<sup>6</sup>).

The experiments reported here have been carried out in order to ascertain whether the replication cycles in the salivary glands occur independently of the moulting cycle or are somehow related to it. Our observations have been confined to larvae from the late second to the late

third instar. This period has been chosen because it is more suitable for our experimental approach.

The entire larval development in our culturing conditions lasts 196 h from the time of oviposition to the early pupa. Based on the presence of shed cuticles on the culture medium, the moult takes place at 116–118 h. The period from 100 to 196 h was divided into eleven periods each of 8 h; the tenth period, however, lasted 16 h.

From synchronous cultures, groups of ten larvae were collected from each period of the development. Tritiated thymidine was administered in the food so that the uptake conditions were as near physiological as possible and the treatment uniform for all larvae<sup>7</sup>. Each group of larvae remained in the radioactive food for 8 h, in standard culture conditions. After incubation, the incorporation of the isotope was stopped by the addition of unlabelled thymidine, and the larvae were transferred to normal food for growth until the early pre-pupa.

In autoradiographs of squashed preparations of the salivary glands, the percentages of labelled nuclei have been calculated for each of the eleven periods (Fig. 1). After an initial period of intensive synthesis in the whole gland, the percentage of labelled nuclei rapidly decreases, reaching a minimum (less than 20 per cent) in correspondence with the moult. A new period of synthesis takes place soon after (70–80 per cent of cells are labelled from 132 to 156 h), followed by a continuous decrease until the puparium is formed.

Fig. 2 represents the distribution of the numbers of silver grains per labelled nucleus; on the whole, this graph is similar to that in Fig. 1. Moreover, it shows that the fairly high percentage of labelled nuclei from 156 to 172 h results entirely from a large number of cells with low levels of uptake (only the 2.3–5.5 per cent of nuclei show

Fig. 1. Percentages of labelled nuclei in the different 8 h periods. As a rule, nuclei with at least twenty silver grains were considered. The counts were made on six slides for each period of the development.

Fig. 2. Average number of silver grains in a labelled nucleus, in the different periods. The grains were counted on fifty nuclei, at random, for each slide.

Fig. 3. Total synthesis in the gland for each 8 h period, represented as the average number of grains/labelled nucleus  $\times$  percentage of labelled nuclei. The continuous curve describes the relative increase of the average DNA content per gland (initial amount = 10).

a number of grains large enough to suggest active synthesis). This situation may arise from the presence of nuclei which are completing their replication cycle or, rather, of nuclei in which, after a complete DNA replication, some DNA synthesis may continue in several active "replicones".

The total synthesis in the gland is represented in the histogram in Fig. 3 as the average number of grains per nucleus  $\times$  the number of labelled nuclei in each sample (300 cells). The shape of the graph shows that a wave of DNA synthesis occurs during the first half of the third instar.

In order to determine whether during this wave of synthesis there are one or more doublings of DNA, a biochemical approach to the problem was attempted. At various stages of the larval development, nucleic acids were extracted according to Schneider's technique and the DNA content determined by Burton's modified DPA method. The extractions were made on 100 pairs of glands for each period of the development, excised from synchronized larvae. The details of the procedure are discussed elsewhere<sup>9</sup>.

The contents of DNA are also reported in Fig. 3. The continuous curve describes the relative increase of the average content of DNA per gland. The curve shows that, in the period of massive synthesis revealed by autoradiography, there is an increase in the amount of the initial DNA of about 4.5 times.

The comparison between the autoradiographic and the biochemical data indicates that in a restricted period of the third instar there is an extensive synthetic activity which leads to an increase of the average content of DNA per gland, corresponding to at least two doublings. Because the synthesis stops at the second moult, resumes, and stops again before the beginning of the metamorphosis, it seems reasonable to relate the perturbation of the cell cycle with the physiological events involved in the moulting cycle.

Results similar to ours have been obtained by Krishnakumaran *et al.*<sup>10</sup> in *Samia cynthia ricini* (Lepidoptera). They observed that "... in the day of the moult to the

fourth instar, synthesis of DNA and RNA was at its lowest during the moult cycle; their synthesis increased during the rest of the instar and reached another low point on the day of the moult to the fifth instar". They concluded that "the stimulation of DNA synthesis is a primary effect of ecdysone".

Becker<sup>11</sup> has shown that in *Drosophila* the release of the ring gland hormone occurs a few hours before the formation of a puparium. It has also been demonstrated that the effect on the metabolism of nucleic acids is almost immediate, as suggested by the appearance of puff patterns within less than an hour of the hormone being injected<sup>6</sup>.

Similarly, other authors think (see Wigglesworth's review<sup>5</sup>) that a high concentration of hormone in insect larvae is reached only shortly before ecdysis.

With our results it is difficult to ascribe the increased synthesis of DNA to the influence of the hormone. In fact, a rapid decrease in the synthetic activity occurs between 108 and 124 h, just when the concentration of the hormone in the haemolymph is quite high; if the effect of ecdysone on the metabolism of nucleic acids is primary<sup>10</sup> and immediate<sup>6</sup>, an activation of the synthetic activity would be expected rather than the over-all arrest which is actually observed in our experiments.

The questions of whether the partial synchronization of the cells synthesizing DNA results from the action of ecdysone, and of whether the ecdysone acts as an activator or an inhibitor, are now being investigated.

We thank Prof. B. Battaglia and Prof. G. Marin for their helpful suggestions in this work.

### Effect of Packaging on the Major Microbial Flora of Irradiated Haddock

A NUMBER of investigations has been made to determine the alterations in the microflora of fish caused by irradiation, and in some cases, the subsequent growth patterns of the survivors during refrigerated storage<sup>1-4</sup>. These investigations have indicated that radiation drastically reduces the Gram-negative micro-organisms normally associated with fish or with fish spoilage and leaves larger numbers of the more radioresistant Gram-positive bacteria and fungi. The nature of the microbial spectrum surviving irradiation depended on the dosage and the initial level of contamination. Subsequent growth of the radiation survivors was then found to be a function of the storage temperature. One variable which has been relatively neglected is the effect of packaging and the accessibility of air on the growth patterns of irradiated seafoods, although certain investigations have indicated that this could be important for ground beef<sup>5</sup> and for poultry packed and canned under nitrogen<sup>6</sup>. In order to evaluate the relationships between radiation, refrigerated storage, and the presence of air, haddock fillets were

packaged in cans without hermetic sealing but covered with aluminium foil to allow free exchange of air (FP), sealed with a limited air headspace (LP), or vacuum packed (VP). The samples were then exposed to 150 krad and stored at 3° C for 3 weeks. For taxonomic identification of the various organisms the determinative scheme of Shewan<sup>7</sup> was used for the Gram-negative organisms. Gram-positive organisms were determined by standard morphological and biochemical criteria. Three per cent hydrogen peroxide was used for detection of catalase, and for cytochromes the benzidine test was used<sup>8</sup>. The results indicated that, in addition to a shift in the major microflora caused by radiation, the microbial spectrum is further altered by the presence or absence of air during refrigerated storage.

The total counts (Fig. 1) of the unirradiated controls (all of which were found to be spoiled after 3 weeks) were much higher for packs FP than for packs LP and VP. After 3 weeks in storage all the irradiated samples were judged by odour and appearance to be in an acceptable condition. The microflora for all samples remained essentially psychrotrophic, as shown by the greatly reduced plate counts at 37° C.

Table 1. THE SELECTION OF *Pseudomonas* BY IRRADIATION AND THE PRESENCE OF AIR DURING STORAGE

<i>Pseudomonas</i> Group	Percentage of microflora					
	Unsealed		Air-sealed		Vacuum	
	U	I	U	I	U	I
I	28	0	0	0	0	0
II	28	4	0	0	9	0
III and IV	4	0	40	0	44	0
Total	60	4	40	0	53	0

U, Unirradiated; I, irradiated.

In the irradiated samples, *Pseudomonas*, the dominant flora in the unirradiated controls, were replaced by the *Achromobacter-Alcaligenes* group which had been present in reduced numbers in the controls. This was especially true for the FP samples (Fig. 2). The three predominant groups present on the irradiated samples were *Achromobacter-Alcaligenes*, *Lactobacteriaceae*, and catalase-positive cocci. The *Flavobacter-Cytophaga* group was only found in a high percentage in the FP samples; the percentage of *Lactobacteriaceae* was highest in the VP and of intermediate value in the LP fillets. Further taxonomic division of the *Pseudomonas* was made and, in agreement with a

Fig. 1. Total aerobic plate counts of samples after 3 weeks storage at 3° C. A 50 g portion of haddock was blended for 3 min with 450 ml. of trypticase diluent. Total aerobic pour plate counts were made in trypticase soy agar supplemented with 0.5 per cent yeast extract in artificial sea water. For each sample, three sets of plates were prepared and incubated at 3°, 20°, and 37° C, respectively.

Fig. 2. Microbial flora of the samples after 3 weeks storage at 3° C as determined taxonomically. (1) *Pseudomonas*; (2) *Vibrio*; (3) *Aeromonas*; (4) *Achromobacter-Alcaligenes*; (5) *Flavobacterium-Cytophaga*; (6) *Paracolon*; (7) Gram-positive cocci, catalase (+); (8) Gram-positive cocci and rods, catalase (-); (9) others (not identified).

recent report<sup>9</sup>, it was found that groups I and II, which were 56 per cent of the microflora, become the dominant flora associated with the unirradiated FP pack. Limiting the available air in the packs, however, caused a shift to the less oxidative groups III and IV, which were 40 per cent for the air sealed (LP) packs and 44 per cent for the vacuum packed (VP) samples. Groups III and IV of the *Pseudomonas* had been found by others<sup>10</sup> to be the major spoilers of unirradiated sole fillets in samples prepared in a similar manner to the LP and VP cases. The spoilage potential of the *Pseudomonas* sub-groups therefore requires further elucidation. One should also consider that in the LP samples carbon dioxide produced by microorganisms during growth may have led to an inhibition of the more oxidative organisms<sup>11</sup>.

It was noted that a large portion (67 per cent) of *Pseudomonas* groups III and IV required sea salts for growth on the various media and also had the highest incidence of proteolytic activity on skim milk agar. Relatively few of the *Achromobacter-Alcaligenes* group were proteolytic whereas a high percentage of the *Vibrio*, *Aeromonas*, and *Flavobacter-Cytophaga* groups were proteolytic. These were usually a small portion of the microbial flora, however, and only a small number of them appeared to require sea salts for growth.

Although higher doses of irradiation might have altered the survival pattern and favoured the survival of micrococci, yeasts, and *Lactobacteriaceae*, only certain of these groups are capable of growth at 3° C.

## FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

## Monday, January 30

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "Ion Implantation" opened by Dr. J. Dearnley and Mr. L. Large.

UNIVERSITY OF LONDON (at Queen Elizabeth College, Campden Hill Road, London, W.8), at 5.30 p.m.—Prof. S. J. Pirt: "The Cultivation of Microbes and Cells" (Inaugural Lecture).\*

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Sir Gordon Sutherland, F.R.S.: "Science" (third of four Cantor Lectures on "Some Aspects of the U.S.A. Today").

PLASTICS INSTITUTE, LONDON SECTION REINFORCED PLASTICS SUB-GROUP (at the Eccleston Hotel, London, S.W.1), at 7.30 p.m.—Meeting on "Timber & Reinforced Plastics for Boat-Building".

## Tuesday, January 31

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.20 p.m.—Prof. G. Belyavin: "Influenza—The Mysterious Scourge".\*

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers and the IEE/RAES London Joint Group, at Savoy Place, London, W.C.2), at 2.30 p.m.—Colloquium on "Adaptive Control for Aircraft".

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. J. R. H. Otter, Mr. A. C. Cassell and Mr. R. E. Hobbs: "Dynamic Relaxation".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion meeting on "Some Recent Developments in Servo-Operated Recorders" opened by Mr. L. A. C. Dopping-Hepenstal and Mr. T. F. Prowse.

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Mr. J. P. von Wartburg (Bern): "Alcohol—Its Effects and Metabolism".\*

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. P. Alexander: "Repair of DNA in Mammalian and Microbial Cells". (Sixth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

SOCIETY OF INSTRUMENT TECHNOLOGY, MEASUREMENT TECHNOLOGY COMMITTEE (at Manson House, 26 Portland Place, London, W.1), at 6 p.m.—Prof. D. de Jong: "Fine Mechanics—The Process from Craft to Science".

## Wednesday, February 1

INSTITUTION OF THE RUBBER INDUSTRY, LONDON SECTION (at the National College of Rubber Technology, Holloway, London, N.7), at 2.30 p.m.—Panel Discussion on "Opportunities in Industry".

ROYAL SOCIETY OF MEDICINE, HISTORY OF MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5.15 p.m.—Prof. J. D. H. Widdess: "The Royal College of Physicians of Ireland and some of its Famous Personalities".

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. R. A. Mostyn and Mr. A. F. Cunningham: "Some Applications of Atomic Absorption Spectroscopy to the Analysis of Fuels and Lubricants".

UNIVERSITY OF LONDON (at the Institute of Laryngology and Otology, Royal National Throat, Nose and Ear Hospital, Gray's Inn Road, London, W.C.1), at 5.30 p.m.—Dr. P. D. Byers: "Pathology of Lesions of Facial Skeleton".\*

SOCIETY FOR ANALYTICAL CHEMISTRY (in the Chemistry Department, Imperial College, London, S.W.7), at 7 p.m.—Mr. C. Whalley and Mr. R. Goulden: "Detection and Determination of Small Quantities of Material".

## Thursday, February 2

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. E. J. Denton, F.R.S.: "On the Organization of Reflecting Surfaces in Some Marine Animals".

ROYAL SOCIETY OF MEDICINE, NEUROLOGY SECTION (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Dr. J. V. T. Gostling, Prof. M. R. Grist and Dr. H. E. Webb: "Viral Diseases of the Nervous System".

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, W.C.1), at 5.30 p.m.—Dr. S. Brenner: "Control and Mechanism of Protein Synthesis". (Seventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation).\*

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6 p.m.—Mr. E. F. Ball: "A Simple Transient-Flow Method of Measuring Thermal Conductivity and Diffusivity".

## Friday, February 3

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albemarle Street, London, W.1), at 1 p.m.—Dr. P. Suppan: "Reactivity of Excited States".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. David Attenborough: "BBC-2".

## Saturday, February 4

ASSOCIATION OF CLINICAL BIOCHEMISTS, SOUTHERN REGION (at the Westminster Hospital Medical School, Horseferry Road, Westminster, London, S.W.1)—Annual General Meeting, followed by a meeting on "Vitamins in Clinical Biochemistry".

## Monday, February 6

UNIVERSITY OF LONDON (in the Botany Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. Gottmann (Paris): "The Growing City as a Social and Political Process. I. City Form and Function in a Changing Society".\*

ROYAL INSTITUTION, LIBRARY CIRCLE (at 21 Albemarle Street, London, W.1), at 6 p.m.—Dr. H. D. Anthony: "The Study of Scenery—2".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. Emil Kekich: "Commerce" (last of four Cantor Lectures on "Some Aspects of the U.S.A. To-day").

UNIVERSITY OF LONDON (at Bedford College, Regent's Park, London, N.W.1), at 6 p.m.—Prof. A. Williams: "British Ordovician Shelly Faunas. I. Palaeogeographic Setting and the Principal Faunas".\*

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. B. J. Hardy: "Some Problems in the Design and Use of Power Cables".\*

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION AND THE INDUSTRIAL MARKETING RESEARCH ASSOCIATION (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. J. A. Nicoll: "A Technique of Long Term Forecasting"; Mr. B. N. P. Hutchesson: "Market Research—Forecasting for the Chemical Industry".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Dr. Alwyn A. Ruddock: "The Earliest English Voyagers Across the North Atlantic".

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

RESEARCH BIOCHEMIST/BIOLOGIST (suitably qualified graduate) to work on immunological and biological aspects of human tumours—The Secretary, The London Hospital Medical College (University of London), Turner Street, London, E.1 (February 2).

LECTURER (qualified biochemist) IN THE DEPARTMENT OF CHILD LIFE AND HEALTH—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh, Scotland (February 4).

SENIOR RESEARCH ASSISTANT in the BIOMECHANICS RESEARCH UNIT for research in the DEPARTMENT OF MECHANICAL ENGINEERING on problems associated with blood flow through valves—The Registrar, The University, Liverpool 3, quoting Ref. RV/353 (February 4).

CHAIR OF TELECOMMUNICATION SYSTEMS within the DEPARTMENT OF ELECTRICAL ENGINEERING SCIENCE—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (February 7).

PHYSICIST (with wide experience of the physical aspects of radiotherapy and radioisotope techniques) to fill a Senior Grade (N.H.S.) vacancy—The Secretary, Mount Vernon Hospital, Northwood, Middlesex (February 10).

LECTURER (educational psychologist) IN EDUCATION—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (February 11).

LECTURER IN THE DEPARTMENT OF PHYSICS—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (February 14).

LECTURER or ASSISTANT LECTURER (well qualified in mycology and general microbiology and preferably with interests in plant pathology, soil microbiology, or microbial genetics) in the DEPARTMENT OF BOTANY—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (February 15).

LECTURER or ASSISTANT LECTURER (with research experience in acoustics) IN PHYSICS—The Secretary, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (February 17).

UNIVERSITY RADIATION PROTECTION OFFICER (suitably qualified graduate) to implement codes of practice throughout the University and to be concerned with radiation work in the area generally—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR, 88C (February 18).

CHAIR OF BIOCHEMISTRY at the Royal Free Hospital School of Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 20).

LECTURER/ASSISTANT LECTURER (with at least a good honours degree or equivalent and capable of undertaking teaching and research in one or more of the following fields: biogeography, hydrology, climatology, oceanography and cartography) in the DEPARTMENT OF GEOGRAPHY, University of Malaysia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, February 21).

LECTURER or ASSISTANT LECTURER in THEORETICAL NUCLEAR PHYSICS—The Staff Officer, University of Surrey, Battersea Park Road, London, S.W.11 (February 23).

ASSOCIATE PROFESSOR, SENIOR LECTURER or LECTURER GRADE I (preferably with experience in medical teaching hospitals) in the DIVISION OF MICROBIOLOGY, DEPARTMENT OF PATHOLOGY AND MICROBIOLOGY, Medical School, University of Lagos—The Inter-University Council, 33 Bedford Place, London, W.C.1 (February 24).

LECTURER or ASSISTANT LECTURER in the DEPARTMENT OF GEOLOGY—The Registrar, The University, Keele, Staffs (February 24).

LECTURER (preferably with suitable qualifications and experience in some area of theoretical or laboratory astrophysics) in ATOMIC PHYSICS—The Registrar, The University, Newcastle upon Tyne 2 (February 25).

LECTURERS or ASSISTANT LECTURERS (2) (preferably with special interests in plant metabolism or algology or mycology) in BOTANY—The Registrar, The University, Leicester (February 25).

SENIOR LECTURER (science or medical graduate) in the DEPARTMENT OF BACTERIOLOGY AND IMMUNOLOGY at the Western Infirmary—Secretary of the University Court, The University, Glasgow (February 27).

LECTURER or ASSISTANT LECTURER (with a degree in biochemistry, physiology, zoology, or veterinary science, and prepared to undertake research in the field of avian physiology) in PHYSIOLOGY—The Secretary, Wye College (University of London), near Ashford, Kent (February 28).

LECTURER and an ASSISTANT LECTURER (qualified in the fields of palaeontology or structural geology) in GEOLOGY—The Registrar, The University, Leicester (March 1).

LECTURER in GENERAL PHYSIOLOGY in the School of Biology—The Registrar, The University, Leicester (March 1).

SENIOR LECTURER/LECTURER (with a post-graduate degree and preferably some experience of teaching biochemistry at university level, and a special knowledge of the agricultural aspects of biochemistry) in BIOCHEMISTRY at Lincoln College, University of Canterbury, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, March 4).

LECTURER or SENIOR LECTURER in BIOLOGY in the field of entomology or applied entomology at the University of Malawi—The Inter-University Council, 33 Bedford Place, London, W.C.1 (March 7).

**HEAD OF THE PROTEIN BIOCHEMISTRY DEPARTMENT** (Senior Principal Scientific Officer grade)—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen, Scotland (March 15).

**RESEARCH FELLOWS/SENIOR RESEARCH FELLOWS** (2) (preferably whose principal interests lie either within the field of social, moral and political philosophy or the field of logic and methodology) IN PHILOSOPHY, Research School of Social Studies, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, March 15).

**UNIVERSITY NUCLEAR PHYSICS RESEARCH FELLOWS** (of Ph.D. standard with a special aptitude for research into high or low energy nuclear physics)—The Registrar, The University, Liverpool, 3, quoting Ref. RV/355 (April 1).

**CHAIR OF ENGINEERING DYNAMICS** at Monash University, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, or The Academic Registrar, Monash University, Melbourne, Australia (Australia, April 17).

**ASSISTANT or ASSOCIATE PROFESSOR** (with a Ph.D. in monogastric nutrition and prepared to teach and conduct research in poultry nutrition) of POULTRY NUTRITION—Head, Department of Animal Science, University of Manitoba, Winnipeg, Manitoba, Canada.

**BIOCHEMIST or BIOLOGIST** (with a Ph.D.) to work in research in the DEPARTMENT OF MEDICINE (possibility of an academic appointment)—Dr. R. A. Camerini, Department of Medicine, New York Medical College, 106 St. and Fifth Avenue, New York, N.Y. 10029, U.S.A.

**EDITOR** (honours degree scientist, preferably physicist with some editorial experience) of the *Annals of the I.Q.S.Y.*, to edit a series of volumes on the results of the International Years of the Quiet Sun sponsored by the International Council of Scientific Unions—I.Q.S.Y., 6 Cornwall Terrace, London, N.W.1.

**FELLOW** (post-doctoral) or **RESEARCH ASSISTANT** in the DEPARTMENT OF CHEMISTRY to study viscosity, molecular relaxation processes and structure of liquids using ultrasonics—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex.

**LECTURER or ASSISTANT LECTURER** in the DEPARTMENT OF SOCIAL SCIENCE and HUMANITIES to teach in the Department's new Social Science Degree course and to contribute to the teaching of sociology to students of engineering and applied science—The Academic Registrar, The City University, St. John Street, London, E.C.1, quoting Ref. 14/SS.

**LECTURER** (with an honours B.Sc. in biochemistry and preferably a Ph.D., with relevant postgraduate experience) in PHARMACOLOGICAL BIOCHEMISTRY in the PHARMACOLOGY GROUP of the School of Pharmacy—The Registrar (S), The University, Bath, Somerset, quoting Ref. 67/3.

**PRINCIPAL LECTURER** IN COMPUTING to be responsible to the Head of the DEPARTMENT OF MATHEMATICS for the organization and administration of the Polytechnic's computer activities—Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

**RESEARCH ASSISTANT** (preferably with experience in modern techniques in gas and blood/gas analysis) to organize a laboratory of the DEPARTMENT OF ANAESTHESIA, and to supervise junior staff mainly for research into subjects associated with anaesthetics and respiratory physiology—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. ASC/841, Project No. 802.

**RESEARCH ASSISTANTS** (2) (postdoctoral chemical engineers, physical chemists or physicists) for (1) highly novel work on detonation threshold phenomena (supervised by Dr. G. Munday); and (2) reaction kinetics in shock-heated homogeneous and heterogeneous systems (supervised by Dr. D. H. Napier)—Prof. A. G. Gaydon, F.R.S., Chemical Engineering and Chemical Technology Department, Imperial College, London, S.W.7.

**RESEARCH ASSISTANTS** (2) (with a good honours degree in mechanical engineering, metallurgy or physics) in ENGINEERING METALLURGY, to work in the DEPARTMENT OF MECHANICAL ENGINEERING on exciting new developments in the prediction of the fatigue life of metals—The Secretary, University College London, Gower Street, London, W.C.1.

**RESEARCH TECHNICAL ASSISTANT** (preferably B.Sc. in microbiology) to assist and participate in a research project concerned with the chemotherapy of synchronous bacterial cultures—The Director, Bland-Sutton Institute of Pathology, Middlesex Hospital, London, W.1.

**SENIOR FELLOW IN HUMAN GENETICS** at the John Curtin School of Medical Research, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1.

**TECHNICAL OFFICER** (preferably with a degree or diploma in agriculture) in the HERBAGE SECTION of the SEED PRODUCTION BRANCH—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

**UNIVERSITY DEMONSTRATOR** IN ORGANIC CHEMISTRY—Dr. P. Maitland, University Chemical Laboratory, Lensfield Road, Cambridge.

## REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

### Great Britain and Ireland

Society for the Promotion of Nature Reserves. Handbook 1966, Forty-ninth Annual Report, year ending 31st December, 1965. Pp. 124. (London: The Society for the Promotion of Nature Reserves, British Museum (Natural History), 1966.) 15s. [1111]

Sponsorship of Music: The Role of Local Authorities. (A PEP Report.) Pp. 77. (London: Political and Economic Planning, 1966.) 10s. [1111]

General Register Office. Studies on Medical and Population Subjects, No. 20: Accuracy of Certification of Cause of Death—a Report on a Survey conducted in 1959 in 75 Hospitals of the National Health Service to Obtain Information on the Extent of Agreement between Clinical and Post-Mortem Diagnoses. By M. A. Heasman and L. Lipworth. Pp. vii+133. (London: H.M. Stationery Office, 1966.) 21s. net. [1111]

Ministry of Agriculture, Fisheries and Food. Bulletin No. 38: Sex-Linkage in Poultry Breeding. Sixth edition. Pp. iv+38+4 plates. (London: H.M. Stationery Office, 1966.) 8s. 6d. net. [1411]

The National Central Library. 50th Annual Report of the Executive Committee for the year ending 31 March, 1966. Pp. 28+3 plates. A Description of the New Building in Store Street opened by Her Majesty the Queen, March 18th, 1966. Pp. 17. (London: The National Central Library, 1966.) [1411]

Cement and Concrete Association. Report for the year 1965. Pp. 72. (London: Cement and Concrete Association, 1966.) [1411]

Government of Northern Ireland: Ministry of Agriculture. Leaflet No. 185: Careers in Agriculture. Pp. 6. (Belfast: Ministry of Agriculture, 1966.) [1511]

The Zoological Record, Vol. 101. Section 7 (1964): Brachiopoda. Compiled by B. F. Owen. Pp. 31. (London: The Zoological Society of London, 1966.) 12s. 6d.; \$1.80. [1511]

Institution of Gas Engineers. Communication 720: 27th Report of the Chairman's Technical Committee—1965-66. Pp. 14. Communication 721: 43rd Report of the Gas Education Committee—1965-66. Pp. 19. Communication 722: Looking Backward at French Natural Gas. By Georges H. Robert. Pp. 20. Communication 723: Automatic Control of Combustion Characteristics. By R. W. J. Andrews, W. H. French and T. A. Lucas. Pp. 12. Communication 724: Institution Gas Research Fellowship Report—1961-63. The Decomposition of Ethane Over Lime Under Continuous-Flow Conditions. By Dr. V. Moran. Pp. 10. Communication 725: The Application of Electronic Digital Recorders to Domestic Load Research. By J. H. Collins. Pp. 16. Communication 726: High-Pressure Measurement. By John W. Harriger. Pp. 6. Communication 727: The Houldsworth School of Applied Science—The Fuel Department After 60 Years. By Prof. A. L. Roberts. Pp. 11. Communication 728: Propane, as Enrichment to Increase Calorific Value and Meet Peak Demands. By L. Langfield, J. L. Wilson, G. A. Woodward and C. E. Sanderson. Pp. 13. Communication 729: Some Fundamental Viewpoints Concerning Gas Quality, Conversion of Appliances, and the Design of Multi-Gas Appliances. By A. van der Linden. Pp. 12. Communication 730: Conversion at Canvey. By R. P. Rhodes. Pp. 14. Communication 731: Trends in the Scandinavian Gas Industry Since 1945. By Norman V. Steenstrup. Pp. 19. Communication 732: The Resistance of Ductile Iron to Corrosion by Sulfur. By D. R. Whitchurch and H. H. Collins. Pp. 9. (32nd Autumn Research Meeting, London, 15th and 16th November, 1966.) (London: The Institution of Gas Engineers, 1966.) [1511]

### Other Countries

United States Department of the Interior: Geological Survey. Bulletin 1214-E: Element Distribution in Some Shelf and Eugeosynclinal Black Shales. By James D. Vine. Pp. iv+31. \$0.20. Bulletin 1222-B: Geology of the Northwest Quarter of the Anaconda Quadrangle, Deer Lodge County, Montana. By Alexander A. Wanek and C. S. Venable Barclay. Pp. iii+28+plates 1 and 2. Bulletin 1222-C: Geology and Mineral Deposits of the Powell River Area, Claiborne and Union Counties, Tennessee. By Arnold L. Brokaw, John Rodgers, Deane F. Kent, Robert A. Laurence and Charles H. Behre, Jr. Pp. iii+56+plates 1-4. (Washington, D.C.: Government Printing Office, 1966.) [711]

Organization for Economic Co-operation and Development. Economic Growth 1960-1970—a Mid-decade Review of Prospects. (Economic Studies.) Pp. 113. (Paris: Organization for Economic Co-operation and Development; London: H.M. Stationery Office, 1966.) 10 francs; 15s.; \$2.50. [711]

Stanford Ichthyological Bulletin. Vol. 8, No. 3: Megalomycteridae, a Previously Unrecognized Family of Deep-sea Cetomimiform Fishes Based on Two New Genera from the North Atlantic. By George S. Myers and Warren C. Freihofer. New Distributional Records of the Butterfly Fish *Chaetodon falciifer*. By Warren C. Freihofer. Description and Osteology of *Lepidarchus adonis*, a Remarkable New Characid Fish from West Africa. By Tyson R. Roberts. Pp. 193-227. (Stanford, California: Division of Systematic Biology, Stanford University, 1966.) [711]

Australia: Prime Minister's Department. The Commonwealth Government in Education. Pp. 56. The Design of Science Rooms. Prepared by The Commonwealth Advisory Committee on Standards for Science Facilities in Independent Secondary Schools. Pp. 56. (Canberra, A.C.T.: Prime Minister's Department, 1966.) [711]

United States Department of the Interior: Geological Survey. Professional Paper 542-D: The Alaska Earthquake, March 27, 1964—Effects on Communities in the Homer Area, Alaska, by Roger M. Waller. With a Section on Beach Changes on Homer Spit. By Kirk W. Stanley. Pp. vi+28+plate 1. \$0.65. Professional Paper 543-C: The Alaska Earthquake, March 27, 1964—Regional Effects. Gravity Survey and Regional Geology of the Prince William Sound Epicentral Region, Alaska. By J. E. Case, D. F. Barnes, George Pfafker and S. L. Robbins. Pp. v+12. \$0.20. (Washington, D.C.: Government Printing Office, 1966.) [711]

Stainless Steel

## MICRO HAMMER MILL

pulverizes almost anything—whether hay, cotton, wool or rock samples.

Only 2 minutes needed to pulverize most samples. Even a few grammes can be ground; maximum charge 120 c.c. Dust-proof closure. Hardened stainless steel grinding mechanism. Slide-in screens for particle size adjustment. Variable speed motor for better grinding control. Price, complete as shown, £78.

## HEATHWAY FOR GLASS WORKING LATHES

Latest design 'S' type lathe

All the HEATHWAY range of lathes have the following features

- ★ Robust construction and lasting accuracy
- ★ Efficient variable speed and easily accessible controls
- ★ Smooth traverses essential to good glassworking

May we send you details of our range of lathes and equipment

# Grey of Norwich lift 5½ tons of microscopes 930 miles in 4 hours

When one of our leading University's requirements was 320 special microscopes by October 10th, D. R. Grey went to more-than-unusually-extreme lengths to see they got them—and on time.

D. R. Grey tracked down their only available source in Europe, completed negotiations within the time set and, on October 7th, chartered a giant Ilyushin aircraft. The same day the Jet was on its way to England with the microscopes on board. Special customs clearance had been arranged ahead and the

microscopes were on the road for their science laboratories within an hour of landing. Result of the whole operation: the University got the microscopes they wanted, when they wanted them... another airport saw its first Ilyushin jet... and D. R. Grey triumphantly upheld their reputation for always delivering the goods on time.

### **Classified Advertisements**

Semi-displayed £4 16s. per single column inch. Minimum £2, each additional 1/12th of an inch 8s. Full page £132. Half page across £66. Colour (orange) £15 extra. 1s. is charged for the re-direction of replies to advertisements with a box number.

ADVERTISEMENTS SHOULD BE ADDRESSED TO: T. G. Scott and Son, Limited, 1 Clement's Inn, Strand, London, W.C.2. Telephone: HOLborn 4743. Telegrams: Textualist, London, W.C.2.

### **APPOINTMENTS VACANT**

#### **UNIVERSITY OF STRATHCLYDE**

#### **DIRECTOR OF AUDIO-VISUAL SERVICES**

In order to develop existing audio-visual services, the University of Strathclyde is seeking to make an early appointment of a Director who has had appropriate experience in this field.

The television centre is equipped with comprehensive closed-circuit television and video-tape recording facilities, and has a photographic unit equipped for both still and cine work. There is a full-time staff of eight.

The person appointed will be responsible not only for the provision and expansion of audio-visual services but also for the development of research and teaching, particularly with regard to university education.

The appointment will be for two years in the first instance and the salary will be within the professorial range.

Further particulars and forms of application (quoting A62/66), can be obtained from the Registrar, University of Strathclyde, George Street, Glasgow, C.1, with whom applications should be lodged by February 18, 1967. (397)

#### **MATHEMATICIAN**

To work mainly on problems associated with the development of mathematical models of combustion processes—including heat transfer and gas-solid kinetics.

Good honours degree is essential. Experience in numerical methods and the application of computer techniques is desirable. The Association possesses a modern digital computer on the site.

Competitive starting salary (reviewed annually) in a range up to £1,350, or in range £1,400 to £1,700, depending on qualifications and experience.

Modern working conditions and wide social facilities. External publication encouraged. Contributory pension fund.

Application forms from the Assistant Secretary, Ref. 3, The British Coal Utilisation Research Association, Randalls Road, Leatherhead, Surrey. (401)

#### **WOLVERHAMPTON HOSPITAL MANAGEMENT COMMITTEE**

##### **RADIOTHERAPY CENTRE**

ASSISTANT PHYSICIST (Graduate) required. Post provides excellent experience in Cobalt-60, X-ray, Radium and Isotope Therapy, and in Radio Isotope Tracer studies. Opportunities for research. Previous hospital experience not essential. Whitley Council salary scale according to qualifications and experience. Appointment will be effective from February 1, 1967.

Applications, with full details and names of two referees, to the Deputy Group Secretary, The Royal Hospital, Wolverhampton, within 10 days of appearance of advertisement. (357)

## **AUSTRALIA COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION**

### **DIVISION OF ANIMAL HEALTH**

## **BIOCHEMIST**

Applications are invited for appointment as Principal Research Scientist or Senior Principal Research Scientist with the Organization's Division of Animal Health, McMaster Laboratory, situated in the grounds of the University of Sydney, with which a close association is maintained.

The principal establishments of the Division of Animal Health comprise: the Animal Health Research Laboratory at Parkville, Victoria; the McMaster Laboratory in Sydney, N.S.W.; and the Veterinary Parasitology Laboratory, Yeerongpilly, Queensland.

The appointee will be required to develop a research programme related to an important problem of the livestock industry and to lead the present biochemical work of the laboratory, which is concerned with certain bacteriological diseases of sheep and with studies on host-parasite relationships, particularly with regard to helminth infections of sheep. At present, five professional workers are engaged in biochemical research and there is a vacancy for another biochemist which could be filled in accordance with the interests of the appointee. Adequate laboratory space, technical assistance and experimental animals are available. The laboratory is well-equipped with modern instruments, including gas-chromatography, spectrometry and those required for radio-isotope studies.

Applicants should have a degree in Veterinary Science or its equivalent, Science, Agricultural Science or Rural Science, and possess either a Ph.D. degree or present evidence of postgraduate research experience and ability acceptable as an alternative. The appointee will be expected to have attained a high reputation as a research worker and to have shown his capacity as a leader of research.

**SALARY**: Depending upon qualifications and experience within the ranges of: \$A7,991–\$A9,209 p.a. or \$A9,625–\$A9,931 p.a.

Salary rates for women are \$A428 p.a. less than the corresponding rates for men.

Promotion within CSIRO to a higher classification is determined by merit.

The duration of the appointment will be determined in consultation with the successful candidate; some applicants may prefer a fixed term appointment for three years, in which case consideration will be given to the continuation of F.S.S.U. arrangements.

Fares paid for the appointee and his dependent family. If the appointee is permanently domiciled outside Australia, return fares will be paid at the conclusion of a fixed term appointment. Further particulars supplied on application to:

Mr. R. F. Turnbull, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2.

to whom applications (quoting Appointment No.: 202/293) should be addressed by the **14th April, 1967**. (428)

## **MARINE BIOLOGISTS NATIONAL MUSEUM OF CANADA OTTAWA, CANADA**

A Canadian Oceanographic Identification Centre, under the sponsorship of the International Biological Programme, has been established at the National Museum to provide identification services in zooplankton, benthos, fishes and phytoplankton for qualified research institutions.

Two positions will be available on April 1, 1967, one to be filled by an experienced biologist who will act as head of the Centre and the second by a more recent graduate.

Applicants should have a Ph.D. plus related experience and publications in planktonology, oceanography and marine biology. Salary will be commensurate with training and experience and will be in the range \$9,500–\$15,000.

**Résumés should be submitted to the Civil Service Commission, Ottawa 4, Canada, quoting file reference 67-100KM. For further information, write to the Director, Natural History Branch, National Museum, Ottawa, Canada. (352)**

## WHAT MR. WEBB SHOULD DO

It is sad that the three American astronauts should have been killed at Cape Kennedy a week ago. They were brave men. Like everybody else, they knew that there must be a fatal accident sooner or later. Indeed, it is a wonder that it has not happened before. Even the irony that the accident now should have happened at a rehearsal, not the real thing, is not entirely unexpected. In the circumstances, of course, it is quite inevitable that Mr. James Webb, the administrator of the National Aeronautics and Space Administration, should have announced that the Apollo programme will continue. Now that so much effort has been spent, it would be folly to turn back.

But what are the chances of success or failure? Mr. Webb would be the last to conceal the uncertainties which remain. Indeed, for several years he has left Congress in no doubt of how the Apollo programme has been trimmed down to its bare essentials, chiefly so as to keep the budget within acceptable bounds. It is no surprise that some of the tasks which remain to be performed before a man can travel to the Moon are almost hair-raising in their difficulty and novelty. The Saturn V rocket still has to leave the ground as an integrated assembly; so far, only the booster has flown on its own. It is unlikely that the landing of Surveyor rockets on the Moon has already provided a good understanding of the difficulties of using rockets as a means of settling gently on a distant surface—though in this respect the intervention of men could be a help and not a hindrance. The problems of arranging for bits and pieces of rockets to reunite in orbits about celestial objects are unfamiliar, to make the lightest of them. Yet hazards such as these have been obvious for some time. The accident a week ago, by contrast, has not previously been given much public attention. Inevitably, the way ahead must now seem even more hazardous than at the end of 1966. If Mr. Webb were now to go to Congress for more money, the chances are that he would have a sympathetic hearing. His difficulty is that he is short of time as well as money. Making the Apollo programme more deliberate would probably imply that the old target of "before the end of the decade" would have to be forgotten.

But would this be a tragedy? Would it matter if the first American to reach the Moon did not arrive until 1970? Or 1971? Or even 1981? The truth is that the objectives which the Apollo programme has set itself are largely arbitrary. They are numbers out of a hat. There may have been something in the argument frequently advanced by NASA at the beginning of the Apollo programme that a tighter programme would be better co-ordinated and even cheaper, but that was always founded on the assumption that the plan proposed was feasible and safe. Now what force it may have had is substantially diminished.

The promise of incidental technological benefits for industry in the United States has not been fulfilled. The side effects there have been do not match in any way the cost of the Apollo programme, and most of those that have some substance are attributable to the whole programme of rocket and satellite development and not just to the part of it concerned with sending men away from the Earth. It is also clear that international prestige is neither dependent on nor won by success in launching men with rockets. The real world is more subtle and more interesting than that, and it has changed a lot in five years. But now even the old Everest argument that Americans must travel to the Moon "because it is there" will seem a little less like courageous daring. Its essential irrationality will be more apparent. In the circumstances, if Mr. Webb has to go back to Congress for a substantial revision of the Apollo programme, he will find more outright opposition as well as more sympathy.

What then should happen? Given the existing commitment to the Apollo programme, it is only sensible to continue. At the same time, however, any means of making the programme more deliberate should be seized on. The extra cost and time involved in mounting more test launchings of the critical pieces of equipment would not be outrageous. If the target of a landing on the Moon sometime this decade should become unattainable, nobody should be made to feel ashamed. But such lessons as there are to be learned from the accident at Cape Kennedy will bear on future programmes, not Apollo. They will serve to reinforce the tendency already apparent in the United States to shy away from spectacular programmes. The budget for NASA for the financial year beginning in July (see page 431) shows that the Administration has taken a sober view of what should lie ahead. There are no funds for further spectacular adventures. Instead, NASA is to be encouraged to make the fullest use it can of the rockets that will have been developed by the end of Apollo. This is sensible, and in line not merely with the recommendations published a year ago by a committee of the National Academy of Sciences in Washington, but also with the growing disenchantment with space travel among people and politicians. In the years since Apollo was begun there has grown up in the United States a healthy preoccupation with real problems on the surface of the Earth. Inevitably, the surface of the Moon has come to seem less exciting and less important. That is entirely as it should be.

## UNIVERSITY GRANTS

THE latest report of the University Grants Committee (see page 434) has done very little to clarify the relation-

ship between the British Government and British universities. In many ways it is a curiously complacent document. Although it recognizes that stresses are accumulating within the system, the committee makes no outward sign to show that it recognizes how far-reaching some of the consequences may be. Instead, the report leaves the impression that the committee is convinced that outstanding problems can be dealt with by comparatively minor changes—an extra deputy chairman here, an extra sub-committee there, and a general exhortation to the universities to look ahead as well as to the past. The trouble, of course, is that the University Grants Committee may be overtaken by events. The demand by the Public Accounts Committee that the books of the universities should be opened to public inspection is a sign of how the wind is blowing, if not a serious threat to academic freedom in its own right. At the same time it is now plain that the universities—and, for that matter, the whole system of higher education—are now so huge and so complicated that a much more professional management is required than circumstances now provide. What is to be done?

The first need is to decide what the University Grants Committee is for. It is a long time since it could serve as a kind of insulator between the public purse and the universities. When the university system was smaller, when the cost of operating it was less, and when university education appeared to be a kind of academic luxury and not a central pivot of a nation's economic strength, it was comparatively easy for the British Government to agree every five years to spend a certain sum of money and then to allow a distinguished and impeccable band of academics to share this out among themselves and their colleagues.

But all this has changed. The government quite properly expects to see that the increasing sums of money spent on the universities are properly spent, and the University Grants Committee has in any case been forced to keep a closer watch on how money is spent in the universities in order that it can make a proper case on their behalf. One obvious danger in these circumstances is that of being turned into a glorified book-keeper—a kind of Auditor-General working from within. Another is that the University Grants Committee, lacking all but the most negative influence on the universities but saddled with responsibility for presenting their case to the outside world, will not be able to urge the universities towards desirable innovation and experiment. Indeed, pushed this way and that as it has been by circumstances, the committee has too often been required to foster uniformity and dullness. There is a case for saying that if it is to continue to exist at all, it should be made stronger and more independent—and more responsible. Indeed, with existing institutions, it is even possible that it will only be possible for individual universities to be given a real sense of their public responsibilities if the University Grants Committee is less committed to the defence of what is called academic freedom, and more

able to thump the table from time to time. The best analogy is that of the nationalized industries and similar public corporations in Britain and elsewhere. The objective is to transfer day-to-day responsibility for some particular task from the government to some other body of men without compromising in any way the right of the government to have its say on broad matters of policy and finance. The corporation is given the responsibility and—just as important—the resources to see that things are well administered. If they are not, presumably the chairman can be sacked. Among the advantages of such an arrangement in the management of the British universities would be that the U.G.C. could then hope to carry out the continuing review of higher education and the demand for it which is essential if orderly progress is to replace the process of transformation by occasional upheaval which served well enough when the system was smaller. In such an arrangement, it would also be possible for the University Grants Committee to carry out the kind of studies on which the qualitative improvement of the university system must in the long run be based. From audio-visual teaching aids and novel kinds of examinations to better means of forward planning, there is a host of innovations to be attempted. As things are, there is a danger that some innovations are overlooked altogether, and that others are tried out on too small a scale in widely scattered universities. A stronger Grants Committee could help enormously to give the system greater cohesion.

But would not a stronger University Grants Committee be as great a threat to the independence of the universities as inspection by the Auditor-General or even direct control by the Department of Education and Science? This is what many academics will instinctively say. The simple answer is that this danger is much less serious than many others. For one thing, there is no reason to fear that an independent corporation asked to find the best match between higher education and the public need would fail to appreciate not merely the importance of real independence in the universities but also the folly of attempting anything else. But in any case, whether the real power lies with departments of government or with the University Grants Committee, there is an urgent need that the universities should be equipped with the machinery of what is sometimes called, in other connexions, collective bargaining. This, with luck, is what the Committee of Vice-Chancellors and Principals will become. In the past few months, the committee has undertaken several tasks which show that its heart is in the right place, though there is still some way to go before it will be in a position to resist all pressure. The most urgent need in the months ahead is to find some way of channelling the energies of the universities through the committee. In the process, it is inevitable that individual universities will have to bury some of their often wayward and idiosyncratic tendencies, but it is in any case time for that to happen.

## NEWS AND VIEWS

### Retreat on Drugs

THE British Government is about to abandon its traditional position on the treatment of drug addiction in the United Kingdom, and to go part of the way to meeting the recommendations of the Brain Committee on Drug Addiction which reported in 1965. In particular, the government will arrange for addicts to be treated at regional centres and not, as at present, supplied with drugs by general practitioners. There is, however, no intention at this stage of making treatment in regional centres compulsory as the Brain committee recommended.

The statement of the British Government's intentions was made in the House of Commons on January 30 when Miss Alice Bacon, Minister of State at the Home Office, agreed with critics of the present position that new legislation would be necessary. Earlier the Minister of Health, Mr. Kenneth Robinson, said that there were now apparently 1,000 people addicted to drugs such as heroin and morphine, an increase of more than a factor of two since 1959 (when there were 454 addicts known to the Home Office). Although the number of addicts in Britain is still small compared with that in the United States and Canada, the rate of increase in recent years has worried the authorities as well as their critics. Although the effects of other drugs such as hallucinogens may be less damaging to an individual than those of heroin and morphine, there is at least reason to suspect that increasing use of these drugs among young people may eventually lead to increasing numbers of adult addicts to the drugs officially classified as dangerous.

To study these questions, the Minister of Health is proposing to establish a research unit at the Institute of Psychiatry of the Maudsley Hospital. As yet there seems to be no approved pattern for the centres at which treatment for drug addiction will be provided. In the debate in the House of Commons the government was criticized for failing to recognize how much financial support would be necessary if the problem is to be treated energetically. More should be known on these matters when legislation is introduced in the early summer.

### Budget for Science

THE balance of public support for science and technology in the United States will not be markedly affected by the budget for the fiscal year 1967-68 published in Washington on January 26. The predicted reduction of the cost of space research and development during the fiscal year from \$5,600 million to \$5,300 million is cancelled out by the increase of defence research and development expenditure, which is expected to increase from \$6,700 million to \$7,200 million. Support for the National Science Foundation and the National Institutes of Health will be modestly increased, as will be the research spending of the United States Department of Agriculture. The most striking feature of the budget, however, is the way in which the United States Government is now embarked

on schemes for controlling the environment, natural and artificial. Although much of this work cannot at present be labelled either as research or development, its growth cannot fail to have important consequences for science.

During the fiscal year to 1968, total expenditure on research and development will amount to \$16,147 million, which is divided almost equally between civil and defence research and development. In the three years 1965-68 expenditures under these heads, together with the expenditure of research and development (as such) by the big spending agencies, are given in the budget as follows:

U.S. RESEARCH AND DEVELOPMENT (MILLIONS OF DOLLARS)

	1966	1967 (est.)	1968 (est.)
NASA	5,350	5,310	5,126
NIH	536	680	662
NSF	176	196	226
Total civil	6,049	7,175	7,180
Total military	7,890	8,381	8,967
Total, civil and military	14,839	15,555	16,147

These figures do not include the \$151 million which the National Science Foundation will spend in 1967-68 on the development of new curricula for teaching science in schools and on other educational activities such as the retraining of teachers. With the growth of other activities, and particularly of the processing and handling of information, the total expenditure of the National Science Foundation will amount to \$455 million (compared with \$395 million in 1966-67).

The increase in the estimated expenditure of the Department of Defense on research and development is largely accounted for by the work now being undertaken to develop a more effective ballistic missile to be launched from a submarine. This same project accounts for some of the expected increase in the budget of the Atomic Energy Commission, although that is partly offset by a reduction in the cost of nuclear space rockets and other devices. The cost of space research and development is being reduced now that the principal expenditure on the lunar landing programme lies in the past, but the National Aeronautics and Space Administration is being given \$82 million to embark on further studies of more distant objectives.

The steady increase in the expenditure of the United States Government on environmental studies and the management of natural resources goes back for at least a decade. In 1968 the Administration is proposing to spend \$3,538 million on projects ranging from the desalination of water (\$28 million) and the control of water pollution (\$229 million) to the management of fish and wildlife resources (\$139 million) and the conservation of soil (\$104 million). Expenditure on new transport techniques and the modern planning of cities is also increasing; for example, some \$250 million will be spent in 1968 on "special projects in model cities". It is expected that some seventy cities will be involved in this programme during the financial year for which plans are now being made.

### Transatlantic Comparisons

THE danger that some European scientists may be affected by "an unjustifiable sense of inferiority" in respect of the United States was one of the themes of an address to the Royal Society of Arts in London on January 30 by Sir Gordon Sutherland, Master of Emmanuel College, Cambridge, and previously pro-

fessor of physics at the University of Michigan and Director of the National Physical Laboratory. According to Sir Gordon, European inferiority is the contemporary equivalent of a sense of inferiority among scientists in North America thirty years ago, and which has now "entirely disappeared". But because the United States, by virtue of its greater population and productivity, is bound to play a much more important part in the development of science and technology, it does not follow that countries such as Britain "should throw up the sponge"; rather, Sir Gordon said, scientists in Europe should reflect how it is possible to make small resources accomplish great things, from radio-astronomy to protein structure.

The reasons for the growth of confidence among American scientists are to be found, Sir Gordon believes, at least in part in the structure of the institutions responsible for higher education and for the management of public expenditure on science and technology. Among the sources of strength in American universities he cited the quality of postgraduate teaching, the flexibility stemming from the absence of a hierarchical structure in university departments and, in particular, the presence of several professors in many departments, the freedom of American universities to compete financially for good staff, the attachment to universities of research centres financed from outside sources, and the fact that university staffs in the United States "have never been ashamed" that research work can sometimes be usefully directed towards practical problems. In his comparison of the arrangements in Britain and the United States for providing public support for scientific research, Sir Gordon was somewhat less envious of arrangements in the United States, although he made it plain that he considers the existence of several government agencies able to spend money on science and technology an assurance that good ideas do not go begging for lack of money. At the same time, he admires the way in which the organization of the budget in the United States makes it possible for "a highly professional group of men" without departmental axes to grind to subject the whole pattern of spending to "central scrutiny and co-ordination". Sir Gordon Sutherland went on to hope that the Zuckerman Committee would emerge as the British equivalent of the Office of Science and Technology in the United States. Speaking of the brain drain, which may be considered a tangible expression of feelings of inferiority or otherwise, he said that "it should not be too difficult to devise self-denying ordinances in the form of quotas for permanent immigration"—a statement that will not easily win agreement.

## What Next for Apollo?

WHETHER the United States Apollo programme will be delayed by the accident which killed the crew of the first spacecraft on January 27 is not yet known. The device, which was due to be launched on February 21 by a Saturn IB rocket, is presumably beyond repair, and statements from Cape Kennedy have suggested that at least three months would go by before another can be brought to the launching site and tested. But the most serious potential delay is that the enquiry now being conducted may make it necessary to re-design some parts of the Apollo system.

The past few months have been plagued by a number of technical troubles. The device in which the fire took place a week ago consisted of two of the three components of the spacecraft intended for the Moon. This has been at Cape Kennedy since October 1966. Early in the programme of testing, the environmental control system failed and a water heater had to be replaced. There has also been difficulty about the fuel cells, which had at various times threatened to produce less power than the project needs. The latest setback will no doubt take even longer to put right.

Even so, it is by no means impossible that the National Aeronautics and Space Administration will be able to land a man on the Moon before 1970—the original target. Indeed, towards the end of last year, some optimists were talking of 1968 as the year in which the first American might land on the Moon. The next step in the programme, which need not be delayed by the accident a week ago, is to launch the Saturn V booster rocket (with 7.5 million lb. of thrust). This test will provide valuable information about the rocket system and will also help to test the efficiency of the heat shields on the Apollo system. Later in 1967 it had been intended to carry out a complicated operation in which the lunar landing capsule would be put into an orbit about the Earth and then occupied, 24 h later, by one of three astronauts launched separately. This experiment will no doubt now be postponed.

## Canadian Appointments

OPERATIONAL Research at Canadian Forces Headquarters in Ottawa has a new Director-General, Dr. George R. Lindsey. He succeeds Dr. R. J. Sutherland, who died recently. Dr. Lindsey graduated from the University of Toronto in 1942, and served with the Royal Canadian Artillery and in operational research with the British Army during the War. In 1946 he worked at the Cavendish Laboratory in Cambridge, and carried out post-graduate work in high energy physics, obtaining his doctorate in 1950. He has worked for the Canadian Defence Research Board, the Canadian Air Force, and the Department of National Defence, and in 1961 was for a year chief of the operations research groups at the NATO station at La Spezia. His work in recent years has been concerned with air defence and ballistic missile defence, and naval matters.

In the background is the question of what Dr. O. M. Solandt will do when his term as Vice-President in charge of Research and Development at Hawker Siddeley of Canada ends shortly. Dr. Solandt, who was a lecturer in physiology at Cambridge in 1939, has also been concerned with operational research. It has been suggested that he might become President of the National Research Council, or return to his old job as Chairman of the Defence Research Board.

## New Radio-telescope

THE Science Research Council has awarded a grant of £45,000 to the University of Manchester for a design study for a new radio-telescope. At the Jodrell Bank Observatory, which will naturally be in the thick of the design process, it is hoped that the new instrument may be a telescope 400 ft. or so in diameter, and capable of high resolution. The cost could easily amount to £4 million—a sum which exceeds by a factor of more

than four the cost of the 250 ft. telescope with which Jodrell Bank pioneered the construction of very large steerable telescopes a decade ago. Evidently the experience of the past few years has persuaded the designers that it will be possible to construct a telescope of this size without presenting the Science Research Council with an impossibly large bill.

As yet, there has been no final decision about the location of the new instrument. It has been arranged that the Atomic Energy Authority should act as an agent for the Science Research Council, supervising the process of design and collecting whatever information will eventually be necessary for making a decision. With luck, design will be complete by the end of this year, so that a prompt decision by the Science Research Council would make it possible to have the new instrument in service by 1972.

## Initial teaching alphabet

In 1960, the University of London Institute of Education and the National Foundation for Educational Research in England and Wales decided jointly to support an experimental study of a simplified and more regular alphabet to be used to teach children to read. The Reading Research Unit, which was formed to undertake the study, has now released its findings (*The i.t.a. Symposium, Research Report on the British Experiment with i.t.a.*, by John Downing, 25s. National Foundation for Educational Research). They justify the enthusiasm of the early pioneers of simplified reading. The alphabet used, Sir James Pitman's forty-four character initial teaching alphabet (i.t.a.), was used in forty-one schools to teach 873 children to read. The same number of pupils were taught by the conventional method. The unit took considerable care that the tests should be as objective as possible, given the notorious difficulties of controlled tests on human subjects.

The children taught with the i.t.a. learned faster than those taught by the normal method. At the age of eight (after three years at school) they were six months in advance of their normally taught contemporaries. Their ability in comprehension tests was greater, and their essays were as much as 50 per cent longer. Curiously enough, the i.t.a. children were even able to spell better after four years than were children taught by the traditional method. The report concludes that "the traditional orthography of English is an important cause of difficulty in learning to read". The children taught with the i.t.a. cannot of course entirely escape the effects of this problem—there is a setback when they finally go over to using the traditional letters, but it is not as great as might have been thought.

The report emphasizes that i.t.a. is not necessarily the best simplified alphabet that can be devised. There is obviously further scope for research into reading and methods of teaching it. Such research might well improve considerably the "productivity" of infant schools, and even pave the way to a simplified alphabet for adults. It is depressing then to find that the report may well have been the last fling of the Reading Research Unit; Mr. Lionel Elvin of the Institute of Education thinks it may be forced to close in May unless further funds are made available. The work of the unit so far has opened up a host of new questions

about teaching methods and it deserves a chance to investigate them more fully.

## Collaboration on Abstracts

THE United Kingdom Atomic Energy Authority has come to an arrangement with *Nuclear Science Abstracts* by which the British literature cited in the abstracting journal will be abstracted in Britain and then sent to the United States for publication. Work on the scheme has already begun and the Atomic Energy Research Establishment at Harwell is responsible for co-ordinating the British effort. The agreement on collaboration, which has the blessing and partial financial support of the Office of Scientific and Technical Information, gives the Atomic Energy Authority responsibility for selecting which items in the British literature shall be abstracted. Later on it is planned that the authority shall also supply *Nuclear Science Abstracts* with indexing terms.

One of the arguments in favour of collaboration is that the libraries of the Atomic Energy Authority are already engaged on similar work to that of *Nuclear Science Abstracts*, so that duplication of effort will be avoided. Similar considerations have led to the decentralization of work on the Canadian and Japanese literature, and no doubt other agreements with *Nuclear Science Abstracts* will follow. To the journal itself, which is at present abstracting nearly 50,000 items a year, it will also be a great advantage that the cost of the operation will be shared with other countries; recently the journal has been under pressure from Washington to ensure that its size and cost do not grow exponentially but, rather, remain constant. At the same time, the efficiency with which the journal has operated since its foundation in 1947 has raised in some quarters the fear that devolution of responsibility may mean less speedy service. From this point of view, further extensions of the international agreement will be scrutinized with care. It also remains to be decided how *Nuclear Science Abstracts* will develop in the years ahead. Changing over to publication on magnetic tape may be tempting but is probably at present unacceptable. Forms of collaboration still have to be worked out with international organizations such as the International Atomic Energy Agency and the EURATOM organization in Europe, both of which are known to be interested in information processing. Yet another possibility, however remote, is that *Nuclear Science Abstracts* will wither away as the subject matter with which it is primarily concerned is transformed either into commercial engineering or into physics, chemistry and other more familiar disciplines.

## Decimal Pound

THE British Government seems to be determined not to change its mind on the decimalization of the British currency. In the House of Lords on January 30, Lord Winterbottom, Parliamentary Secretary at the Ministry of Public Building and Works, said that the government did not believe the difficulties of making a transition to the system based on a pound rather than a unit half as big would be anything like as great as critics made out. He suggested that the critics were trying to frighten ordinary people and that the decimal currency board would ultimately launch a campaign

of public education to put people's fears at rest. Lord Halsbury, the chairman of the committee which recommended that the pound rather than ten shillings should be used as the basic unit, backed up the government with the argument that the choice of the pound would ensure that people were not cluttered up with "unwanted coins". And Lord Shackleton, opening a debate on the subject for the government, said that, even though he welcomed the opportunity for discussion, it should be clear that "the government had made up its mind".

## University Money

THE University Grants Committee this year combines its annual report with the review of university development in Britain in the first four years of the present quinquennium from 1962-64 (H.M.S.O., Cmnd. 3192, 4s.). The committee, now twenty-one strong and on a part-time basis, rejects suggestions that it should be radically reduced in size and made professional. Its present size is "probably about right". The U.G.C. now has more sub-committees from which it can seek advice; new ones, covering Arts, Audio-Visual Aids, Biological Sciences, Education, Mathematics, Physical Sciences and Social Studies, have been set up.

The new quinquennium—the five-year period for which the U.G.C. establishes grants—begins on August 1, 1967. Grants for the whole period will not be announced for several months, but a provisional announcement has already been made of the minimum level of the recurrent grant in the first year of the quinquennium. On December 20, 1965, the Secretary of State for Education and Science said that the recurrent grant (which excludes capital investment in building and equipment) would be £147.5 million. This figure excludes the cost to the U.G.C. of taking over certain research projects from the research councils and also a contribution of roughly £6 million which the central government will eventually make towards local authority rates (taxes). The comparable figure for 1966-67 is £133.2 million, which implies an increase of 10.7 per cent. The U.G.C. has now allocated this sum to the individual universities so that they can plan their recruitment of staff for 1967-68 and also indulge in more elaborate forward planning if they are so inclined. The U.G.C. is plainly hoping to encourage the universities to make fuller use of modern management techniques. Organization and method can hardly be said to be spreading like wildfire through the British universities, though, and the U.G.C. has enlisted the Committee of Vice-Chancellors and Principals to fan the flames. Organization and method exercises have been mounted in north-east England and in Scotland; several other universities, the report hints, are about to take the plunge.

The report also announces a new type of grant which should be available in 1968-69, if any university is thinking ahead that far. This will be an equipment grant, designed to enable universities with old departments to re-equip them occasionally. At present new equipment is supplied with new buildings, so that university departments tend to be either new from top to bottom, or antique both in fabric and equipment. Most, of course, have been buying equipment piecemeal from their recurrent grants, but the new proposals would make special grants available for this purpose.

After the publication of the report, Sir John Wolfenden, chairman of the U.G.C., suggested that an investigation of the way university laboratories are used might well be profitable. Once again the U.G.C. is nominating the Committee of Vice-Chancellors and Principals for the job, in collaboration with the Confederation of British Industries. (The investigation would be on the same lines as that conducted by Sir Gordon Sutherland and his committee into government laboratories, which will shortly be published.) Sir John Wolfenden also said that universities which are deterred from undertaking research contracts from industry because these are short-term operations should get in touch with the U.G.C., which will occasionally be prepared to take over in the same way as it has been doing for contracts with the research councils.

## Nottingham Agriculture

THE University of Nottingham has decided to amalgamate the departments of agriculture and horticulture into one "Faculty of Agricultural Science". This decision will no doubt bring cheer to the University Grants Committee, which has recently been attempting to encourage the rationalization of agricultural teaching at British universities. The registrar at Nottingham, Mr. A. Plumb, explained earlier this week that the university had suggested a "re-alignment" in view of the imminent departure of the professor of agriculture, Dr. J. P. Hudson, for Bristol, and had not had to wait for prompting from the U.G.C. A statement by the university says that the present department of agricultural sciences will be divided into two—a department of physiology and environmental studies and a department of applied biochemistry and nutrition. This will emphasize the increasingly scientific character of agricultural education. The school of agriculture at Nottingham is in fact the second largest in Britain with an entry of 93 undergraduates in 1965-66 and with five professors, two readers and 26 lecturers on the staff. The department of agricultural economics will be unaffected by the proposed change.

## Living on Air

A boost in British hovercraft development may result from a decision announced by the Minister of Technology, Mr. Anthony Wedgwood Benn, on January 24. The Technical Group of Hovercraft Development Ltd., a subsidiary of the National Research Development Corporation, is on April 1 to become the responsibility of the National Physical Laboratory. Almost all the activities of Hovercraft Development Ltd. were concentrated in the Technical Group at Hythe, so that NRDC is left with little but the power to issue licences for hovercraft development. The move seems sensible if only to make use of the considerable experience of the Ship and Aerodynamics Divisions at the NPL; the Ship Division has been working on air cushion vehicles for some time, both in collaboration with HDL and on its own account. The performance of free flight models in waves has been studied, in experiments designed to be of direct value to hovercraft engineers. A constant force towing dynamometer using a slipping clutch has been designed, allowing the model to surge 30 ft. downstream quite freely, and minimizing the risk that it will overturn.

More rapid progress would be welcome, since developments elsewhere in the world are beginning to make British efforts look leaden footed. In France, the Aerotrain test vehicle, propelled by a temporary rocket attachment, reached a speed of 188 m.p.h. along its short test track recently. In Britain, the corresponding project is still at the model building stage, and seems to have raised no enthusiasm in British Rail. On the naval side, there is interest in vehicles in which the sidewalls are immersed so that the air cushion is trapped; these are particularly suitable for comparatively low speeds. Military strategists on both sides of the Atlantic should by now have firm ideas about how useful hovercraft are likely to be in a military role, since both the United Kingdom and the United States have used them in operations in the Far East.

At the moment, too many hovercraft projects in Britain seem to be hanging fire, which makes it easy for American companies to coax British engineers to emigrate. NRDC, whose source of funds is now the Ministry of Technology, has spent more on hovercraft than on any other project, but the total since 1958 is only £2.5 m. This is derisory in comparison with the share in the Anglo-French variable geometry project—at least £100 m—which Britain has cheerfully taken on. Perhaps Mr. Benn's enthusiasm will divert similar largesse towards the NPL when it starts work; until then the British effort, like the hovercraft themselves, appears to have no visible means of support.

## X-Ray Camera

THE resolution of X-ray diffraction patterns is increased if the X-ray beam is well collimated. While good resolution is always important in crystallography, it is particularly important when partially ordered materials are being studied, since even in the ideal case the patterns are likely to be diffuse. If very fine apertures are used to provide a collimated beam, the exposure time is greatly increased, and may run into weeks. The Franks camera, commonly used for work on partially ordered materials at low Bragg angles, focuses and collimates the beam by reflexion from two mirrors at grazing incidence, but suffers from the disadvantage of a very low angular aperture. Reflexion at grazing incidence has now been used by Dr. A. Elliott of the Department of Biophysics at King's College, London, for a new camera which he has developed for work at higher Bragg angles. (For spacings  $< 50 \text{ \AA}$ .)

In Dr. Elliott's camera the X-ray beam is focused as it passes along a capillary tube the internal profile of which is barrel-shaped. The tube, about 3 mm wide at its widest point and several cm long, is coated internally with gold, which has the highest known reflexion for X-rays. Even so, for copper  $K\alpha$  radiation the glancing angle is only about  $\frac{1}{2}^\circ$ ; a similar design built in the United States by Henke and DuMond (*J. Appl. Phys.*, **26**, 903; 1955) was not suitable for X-rays of wavelength shorter than aluminium K radiation, for which the glancing angle is three times greater. Dr. Elliott has succeeded in producing a mirror small enough for use with copper  $K\alpha$  radiation by a casting technique with epoxy resins.

The camera is suitable for high angle work; the difficulty at low Bragg angles is that scattering of the main beam interferes with the pattern. At high

angles, however, the camera gives about a ten-fold increase in intensity and very good definition, as well as acting as a monochromator. The high angle diffraction pattern of muscle has been studied in greater detail than before, and liquid crystals have also been studied (Parry and Elliott, *Nature*, **206**, 616; 1965). The design can also be used in powder cameras, and is being used in X-ray fluorescent analysis by Mr. R. W. Fearnhead at the London Hospital Medical College. The method has not yet been applied at King's for the study of active muscle, despite the impression given by a previous item in *Nature* (**212**, 969; 1966), but it is hoped that this will be done in the future. The advantages of the camera should become more generally available soon, when it is marketed commercially.

## Geophysics in India

THE annual meeting of the Indian Geophysical Union was held on January 5 this year. In his presidential address Dr. M. S. Krishnan spoke about the structure of south-east Asia with particular reference to the Mesozoic and Tertiary island arcs. The chief guest at the meeting was Dr. Atma Ram, Director-General of the Indian Council of Scientific and Industrial Research, who emphasized the importance of geophysics in exploring the natural resources of the country at a time when India desperately needed natural resources. The Krishnan medal for the year 1966 was awarded to Dr. H. M. Iyer for his outstanding contribution in the field of seismology. The medal for 1965 was presented to Dr. D. Lal at the meeting. Honorary Fellowships of the Indian Geophysical Union were conferred on the following: Dr. K. R. Ramanathan, Dr. Maurice Ewing, Dr. Tuzo Wilson, Professor V. V. Belousov, Sir Edward Bullard, Dr. T. Nagata and Madam Kosminskaya.

## East African Academy

MAN in his East African environment was the principal theme of the fourth symposium of the East African Academy, which was held in Kampala in September. In the opening address the vice-president of Uganda, Mr. J. K. Babuha, challenged the academy not to "look at East Africa and its problems from the dizzy heights of [an] academic ivory tower", but to use its knowledge to help the less fortunate to a better way of life. In five plenary sessions, evolutionary and cultural aspects of life in East Africa were discussed. The role of nationalism, urbanism and tribalism in contemporary Africa was examined, and in another session the changing pattern of disease and the effects of environmental change on this were traced. In a special plenary session the president of the academy, Dr. W. K. Chagula, discussed the role of the educated East Africans in developing their countries, and Dr. Chidzero of the United Nations, from Nairobi, in the distinguished lecture—a new feature of this symposium—examined the reasons for international aid programmes and the need to expand them. These programmes must be synchronized with local efforts if living standards are to be much improved. There is a danger, he warned, of using economic assistance either to provide jobs for international civil servants or as a camouflage to sabotage the political independence of recipient countries.

Four of the physics papers, given in the disciplinary section, were geophysical in content, which reflects the fact that perhaps 80 per cent of physics research in the three colleges of the University of East Africa is concerned with investigation of the environment. An Institute of Tropical Geophysics was proposed, as a centre of expertise and a stimulus for the progress of physics in tropical universities. Half of the biological papers given were parasitological, most of them from the East African Trypanosomiasis Research Organization; much research into sleeping sickness, which has long been a barrier to human settlement and farming activities, is in progress. The possibility of using antigenic classification for trypanosomes was discussed in relation to the biological control of the disease in cattle. A survey of trypanosomiasis in the fly-belt region revealed that the area of tsetse fly invasion is increasing, mainly because of the encroachment of game into some stock areas. Another zoological paper described how the breeding seasons of equatorial free-tailed bats coincide with the rainfall peaks of Uganda. Such research is valuable, for at least fourteen different viruses have been isolated from bats at the East African Institute of Virus Research.

### Nature by Regions

DURING 1966, 3,387 scientific communications of all kinds were published in *Nature* and the following list shows that these originated in a total of 59 countries. As in previous years, the United Kingdom and the United States each contributed roughly a third of them. The countries of the British Commonwealth and Western Europe were the principal sources of other communications although contributions from Japan and the Soviet Union are a large and growing feature of the journal. It is now some years since there have been communications to *Nature* from the Chinese People's Republic.

### Parliament in Britain

IN reply to questions in the House of Lords on January 23, Baroness Phillips said that outbreaks of disease affecting salmon, sea trout and brown trout had occurred during the past two months in the rivers Conder, Crake, Gilpin and Kent in Lancashire, the River Eden in Cumberland, and the rivers Dee, Annan and Nith in south-west Scotland. The position was sometimes obscured by the natural mortality among spawned fish at this time of year. In a written answer in the House of Commons on January 24, Mr. J. Hoy, joint parliamentary secretary, Ministry of Agriculture, Fisheries and Food, stated that extensive tests at the Waterville fish farm and on fodder fish elsewhere had disclosed no grounds for believing that the farm is responsible for the disease. The cause had not yet been established, but a leading authority in the United States had stated that he had not found among infected salmon in Ireland the particular organism responsible for columnaris disease in open waters and in some fish hatcheries in America: neither had that organism been isolated from stocks of rainbow trout or from fodder fish used in the Waterville fish farm.

IN reply to questions in the House of Commons on January 24, the Minister of Technology, Mr. A. Wedgwood Benn, said that the terms of reference of the Advisory Board on Relations with the Universities, set up with Dr. S. C. Curran as chairman, were "to consider and report on proposals for the formation and development of Institutes of Advanced Technology and to keep under review collaboration between the Ministry of Technology and the universities and other higher educational establishments on projects designed to promote technological progress in industry".

IN written answers on the same day, Mr. Benn stated that in the financial years 1965-66, £365,000 of Government money was committed to the computer industry under the Advanced Computer Techniques Project while the National Research Development Corporation had made a further £1.6 million available. Development since the National Electronics Research Council was set up in July 1964 had profoundly affected the role of the Council which would now become the National Electronics Council under the Ministry of Technology with a more limited interest in research but responsibility for the impact of major developments in electronics on society. It would consider and advise the Government on the application of electronics to national life and, if it saw fit, would take steps to promote research or other actions. The membership of the governing body of the Council would be widened and the Secretariat would be provided by the Ministry of Technology.

IN reply to questions in the House of Commons on January 24, Dr. J. Bray, parliamentary secretary to the Ministry of Technology, said that construction of the Steam Generating Heavy Water Reactor at Winfrith Heath was on schedule and it should be on power this autumn. Government expenditure of £85,000 on whisker technology last year was shared by the Ministry of Aviation, the Atomic Energy Authority and the Science Research Council. The future of the programmes in this expanding field was currently under review and there was room for an increase in the £5,000 at present sponsored with the universities.

## University News:

## Edinburgh

PROFESSOR W. L. M. PERRY, professor of pharmacology, and Professor D. Talbot Rice, professor of fine art, have been appointed vice-principals of the university as from January 23.

## London

DR. L. HOUGH, reader in the University of Bristol, has been appointed to the chair of chemistry, tenable at Queen Elizabeth College. The title of professor has been conferred on the following: Dr. P. Alexander (radio-biology, in respect of his post at the Institute of Cancer Research: Royal Cancer Hospital); Dr. D. F. Cheeseman (biochemistry, in respect of his post at Bedford College); Dr. D. R. Hughes (mathematics, in respect of his post at Westfield College); Dr. J. F. McGhie (organic chemistry, in respect of his post at the Chelsea College of Science and Technology).

## Manchester

DR. F. LIONS, of the University of Sydney, has been appointed to a nine months visiting readership at the university. Dr. Lions, whose appointment has been financed by a Science Research Council grant, is a leading authority on the synthesis of heterocyclic compounds.

## Appointments

SIR HAROLD HIMSWORTH, Secretary of the Medical Research Council, has been appointed Deputy Chairman and a member of the Council for the duration of his tenure of office as secretary. Lord Platt becomes a member of the Council.

## Announcements

At the end of the annual Winter Meeting of the American Institute of Physics this week in New York, Dr. Charles H. Townes, professor of physics at the Massachusetts Institute of Technology, assumed office as president from Dr. John Bardeen of the University of Illinois. The president-elect is Professor Luis Alvarez of the Lawrence Radiation Laboratory of the University of California at Berkeley, who works in high energy physics. Dr. William Havens of Columbia University has been appointed executive secretary of the institute, and will assume most of the duties of Dr. Karl Darrow, who has been secretary for 26 years. Other appointments to the council are Dr. Shirley Quimby (Columbia University), who will be treasurer, Dr. Walter Gordy (Duke University) and Dr. Robert R. Wilson (Cornell University). Dr. Samuel Goudsmit, hitherto managing editor of the professional publications of the American Institute of Physics, is now to be known as editor-in-chief. He remains the senior of the two editors of *Physical Review Letters*.

THE Linnean Society medals and awards have been awarded to the following: *The Linnean Gold Medal* to Dr. C. E. Hubbard, formerly of the Royal Botanic Gardens, Kew, and C. S. Elton, director of the Bureau of Animal Population, Oxford; *The H. H. Bloomer Award* to Mr. A. G. Long, of Berwickshire High School, Duns, Berwickshire; *The Trail-Crisp Award* to Professor J. Heslop-Harrison, of the University of Birmingham.

THE Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members in the sections indicated: *Mathematics*, Prof. M. Deuring (Göttingen); *Chemistry*, Prof. H. Kölbl (Berlin); *Physical Chemistry*, Prof. I. N. Stranski (Berlin); *General Biology*, Prof. M. Hašek (Prague); *Anatomy*, Prof. D. A. Shdanov (Moscow); *Physiology*, Prof. P. G. Kostjuk (Kiev); *Neurology*, Prof. B. Horányi (Budapest); *Dermatology*, Prof. F. Földvari (Budapest) and Prof. W. Ocklitz (Berlin); *Stomatology*, Prof. I. Reichborn-kjennerud (Oslo);

*Hygiene*, Prof. D. Blaškovič (Bratislava), Prof. G. Piekarski (Bonn) and Prof. E. Witebsky (Buffalo).

SIR EDWARD BULLARD is to give the annual Bakerian Lecture of the Royal Society of London.

THE Horticultural Trades Association is offering a prize of £20 for a description, in 90 words or less, of the "F.1 hybrid seed process". The intention is that the "ordinary man in the street" should be able to understand it.

THE London International Engineering and Marine Exhibition and the International Welding Exhibition are to be held in London during April 25–May 4.

THE Lighting Exhibition will be held at Earls Court, London, during April 25–May 4. Further information can be obtained from F. W. Bridges and Sons, Ltd., Commonwealth House, 1–19 New Oxford Street, London, W.C.1.

THE third European Congress of Neurosurgery, organized by the Belgian, Dutch and Portuguese–Spanish Societies of Neurosurgery, will be held in Madrid during April 23–26. Further information can be obtained from Dr. S. Obrador, Eduardo Dato, 23, Madrid 10.

AN international symposium on "Physical Separation Methods in Chemical Analysis", organized by the Analytical Chemistry Section of the Koninklijke Nederlandse Chemische Vereniging, is to be held in Amsterdam during April 10–14. Further information can be obtained from Dr. C. L. de Ligny, Analytical Chemistry Laboratory, The Rijksuniversiteit, Utrecht.

THE twenty-first annual symposium on fundamental cancer research entitled "The Proliferation and Spread of Neoplastic Cells", sponsored by the University of Texas M. D. Anderson Hospital and Tumor Institute, Texas Medical Center, will be held in Houston during February 27–March 1. Further information can be obtained from The University of Texas, M. D. Anderson Hospital and Tumor Institute, Houston, Texas.

A CONFERENCE on "Spark Discharges", organized by the Atomic and Molecular Physics Sub-Committee of The Institute of Physics and The Physical Society, is to be held in the University of Liverpool during April 5–7. The topics will be restricted to spark discharges in gases. Further information can be obtained from the Meetings Officer, The Institute of Physics and The Physical Society, 47 Belgrave Square, London, S.W.1.

THE second international congress for stereology, organized by the International Society for Stereology, will be held in Chicago during April 8–13, under the auspices of the National Science Foundation, the Chicago Medical School and the Chicago Academy of Sciences. Further information can be obtained from the International Society for Stereology, 2020 W. Ogden Avenue, Chicago, Illinois.

A SYMPOSIUM on "Lubrication and Wear in Living and Artificial Human Joints", organized by the Lubrication and Wear Group of the Institution of Mechanical Engineers in association with the British Orthopaedic Association, is to be held at the Institution of Mechanical Engineers on April 7. Further information can be obtained from E. P. Davies, Head of Groups Dept., The Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

ERRATUM. In the communication "Depression of Muscle Spindle Function with Vincristine" (*Nature*, 212, 90; 1966) the dose of vincristine given in the twenty-second line should be 2.0 mg/m<sup>2</sup>.

ERRATUM. In the article "Dielectric Absorption of Microwaves in Human Tissues", by J. R. Mallard and D. G. Lawn, which appeared in *Nature*, 213, 28; 1967, the second formula on line 1 of page 29 should read

$$B_j = \begin{bmatrix} e^{i\varphi_j} & 0 \\ 0 & e^{-i\varphi_j} \end{bmatrix} \begin{bmatrix} 1 & R_{j+1} \\ R_{j+1} & 1 \end{bmatrix}$$

# Money for Universities

by our Special Correspondent

Should university finance be subject to inspection by the Comptroller and Auditor-General? The Committee of Public Accounts of the House of Commons has recently considered the question, and has recommended that inspection should begin in 1967-8. The minutes of evidence taken by the committee show that many people doubt the wisdom of this decision.

SIR JOHN WOLFENDEN, chairman of the University Grants Committee, told the committee how the U.G.C. finances the universities. The five year block grant, he said, was seen as imposing on the universities a very serious responsibility. "A university knows for five years in advance, at any rate at the beginning of the quinquennium, what its income will be, and within that income it must stay." The academic in-fighting in the senate, Sir John said, means that if a university spends its money on one thing it cannot spend it on another; this is a built-in inducement to economy. By nature, he added, universities are bound to try to be economical, though he doubted if that was quite the same thing as knowing in detail how to. Asked if the U.G.C. consults the Department of Education and Science about the more expensive building projects, Sir John said that the criterion of cost was not discussed. The arrangement seems to be that the U.G.C. submits a list of building starts to the department, and if the total falls beneath the ceiling established for that year's building starts, the list is approved. Any building start of value more than £30,000, however, is examined individually by the department. Being more specific about the procedure, Sir John described it in terms of a three phase process; first, the universities tell the U.G.C. what they want to do. Then the U.G.C. finds out from the D.E.S. how much money is going to be available, and knowing this, reconsiders the bids submitted by the universities and decides which are the best to back within the ceiling set. D.E.S. approval is then likely to be a formality.

## Cost Control

Moving to cost control, Sir John said that his experience had convinced him that the universities would not object to an exercise in cost control; the difficulties that the U.G.C. had found in trying to work out the costs of an individual student had been caused by the crude and unsophisticated way that it had set about it. Sir John went on to add that there was a danger in this sort of accounting—"I would really rather earnestly plead that this is not simply an arithmetical matter . . . if examination by the Comptroller and Auditor-General resulted simply in pressure for an arithmetical formula as the controlling thing, then I would be very sorry". Sir John also spoke of "centres of excellence", a phrase for which he expressed some distaste. The concept, however, he seems to accept, with the reservation that "it is not really an either/or situation, that you have got to have concentration and specialization, or you are landed with a uniform spread which can only result in mediocrity. . . . I think we have got to combine the best elements of both".

In its memorandum to the Public Accounts Committee, the Committee of Vice Chancellors and Principals expressed its fears about the involvement of the Comptroller and Auditor-General in university finance. The principle that the D.E.S. should not interfere with

university freedom was not at issue, the memorandum says; this is agreed by everybody. What was at issue was whether the investigations by the Comptroller and Auditor-General would involve the D.E.S. in parliamentary controversy which would in turn force the department to take a much more detailed interest in university expenditure. The D.E.S. would no longer remain at one remove from the universities, with the U.G.C. acting as a buffer, and this would be damaging to the universities, whose efficiency is "a function of their academic freedom and initiative". This theme is the basis of the memorandum, and it was expanded when the committee gave evidence. Asked by the chairman of the Public Accounts Committee, Mr. Boyd-Carpenter, whether the committee would find control by the U.G.C. more or less objectionable than control by the department, Sir Charles Wilson said that he thought it would be less objectionable, but that it would certainly be followed, in his opinion, by an increase of control by the department. He agreed that intervention by the U.G.C. in "housekeeping details" of university expenditure had increased in recent years, and suggested cautiously that this might have reduced academic freedom. The area of discretion left to the universities was, he thought, vital.

Asked to give a concrete example of the way in which he felt examination by the Comptroller and Auditor-General would be an intrusion into university freedom, Sir Charles quoted the example of his own university, the University of Glasgow. In the medical school, a change had been made in which the fourth year of the five or six year course had been turned into an integrated year, in which everybody was taught together. The cost of this experiment had turned out to be considerable. How could one say whether the experiment was good value for money? The Comptroller and Auditor-General, Sir Bruce Fraser, replying, said that if he were auditing the books and found an increase of this type, he would ask why. If he were told that the increase had come about as a deliberate decision of academic policy, that is all he would wish to know. "I would say no more about it. It would be ridiculous for me to try to substitute my judgment for the academic judgment of the people who know about it. This is not the way the Comptroller and Auditor-General ever, ever works." Sir Charles Wilson said that if his fears had been based on a misunderstanding of the memorandum prepared for the Public Accounts Committee by the previous Comptroller and Auditor-General, he would be glad to have misunderstood it. The original memorandum had, he thought, been more wide-ranging than Sir Bruce Fraser had suggested.

## Hospitals

The discussion then turned to the hospitals, which are subject to the inspection of the Comptroller and Auditor-General. Sir Robert Aitken said that he thought that adverse consequences had followed from this inspec-

tion; the controls were closer, and the machine operated much more slowly. Sir Bruce Fraser, drawing on his previous experience as Permanent Secretary of the Ministry of Health, said that it was not the audit but the fact that the ministry had never provided enough money which had caused this situation.

Mr. Sheldon of the Public Accounts Committee suggested that it was unreasonable to object to an audit by the Comptroller if the universities were prepared to accept increasing control by the U.G.C. "It seems very much like the question of just accepting the devil one knows even if his horns are growing rapidly", he said. Sir Charles Wilson replied that U.G.C. control might be acceptable alone, but increased departmental control in addition would be too much. "It is to pile Pelion upon Ossa", he said.

The Association of University Teachers, which met the Committee of Public Accounts two days later, was treated far less tenderly, probably because it criticized the effect the committee's decisions about Cranfield Aeronautical College had had on the morale of the staff and, by implication, on the quality of the research carried out there. Dr. T. G. Halsall of the University of Oxford said that Cranfield was the single example available from which inferences could be drawn, and from the information he had received from colleagues there, the recommendations of the Public Accounts Committee were incompatible with the freedom to conduct the pattern of research which they would wish to conduct. This stung the chairman of the committee into a brisk exchange. "Are you aware that as a result of this committee's investigations in Cranfield, very considerable economies were achieved?" Dr. Halsall replied, "I understand, sir, at the expense of very considerable developments and research". On academic freedom, Dr. K. Urwin, the general secretary of the association, suggested that there was greater emphasis on supplying places at universities for science and technology students than for arts students. This made it very much easier for a mediocre student to get in to read scientific subjects than to read arts subjects. If this trend were to continue, it might be interpreted as an intolerable infringement of academic freedom, although this was not yet the case. The association did not think that inspection by the Comptroller and Auditor-General would make this situation worse.

### Cost Effectiveness

The difficulties of deciding when money is well spent were well illustrated by one exchange. Professor Griffiths asked if this meant universities should get tenders before they bought things. "That is one element of it," replied Sir Douglas Glover of the Committee of Public Accounts. "We do that now," said Professor Griffiths. "The point is, if we took the lowest tender, a Japanese estimate, which caused us to spend valuable money outside the country, would that be well spent?" The association repeated an argument used by the U.G.C. that the real safeguard for public money in university research was the fact that there was never enough of it, so that the internal struggles made sure that it was not wasted. Mr. M. Hookham of the University of Leicester said that the tenacity with which university lecturers fought proposals which they believed to be a waste of money was really quite remarkable. "Even the university chancellors do not know with what intensity this sort of thing is watched."

The committee was more deferential to its next witness, Lord Butler of Saffron Walden, among other things a former Minister of Education. Lord Butler said that there were dangers in enlarging the access of the Comptroller and Auditor-General to the detailed books and papers of the U.G.C. He said that it really was possible to criticize the shortness of money and expenditure rather than the laxity of the amount of money spent. His case rested on the psychological effect which the proposals would have, rather than any specific intrusion into university freedom.

His claim that "Dictatorship always starts by detailed criticism of the universities" did not, he said, imply any criticism of the present government. Lord Franks, Provost of Worcester College, Oxford, said that if the Comptroller and Auditor-General was to investigate universities, his net might well be spread even wider. "It is not obvious to me why, if this is the proper scope of the Comptroller and Auditor-General, he should not, on the same reasoning, have access to the records to the books and records of many other bodies besides the universities—for example, the nationalized industries, the BBC, local government authorities, and indeed, private companies doing work under contract to government, especially where a great part of their work is of this kind". He added that he had had the impression that the activities of the Comptroller and Auditor-General resulted in a steady pressure towards uniformity.

### Auditing

Lord Murray of Newhaven, Chancellor of the University of Southampton, feared that auditing would necessarily involve the Department of Education and Science more closely with the universities. "I think that the accounting officer would have to protect himself to meet his obligations as accounting officer for the universities. . . . I think it would be difficult for him to stop at asking why as well as what expenditure is incurred". Lord Heyworth, a former member of the U.G.C. and a former chairman of Unilever, Ltd., said that the position of the academic members of the U.G.C. was delicate: "Only by the fact that nobody knows who contributed to what can they still retain the respect of their colleagues, and the U.G.C. can retain its authority". He said that central control would necessarily need formulae, and he did not believe that formulae were a reasonable means of reaching this kind of decision. "The interrelation between teaching and research elevates the element of judgment to such a degree that it really changes the whole operation".

Lord Robbins, Chairman of the Committee on Higher Education, held to the line established by his committee. "I regard the U.G.C. with its present functions as one of the most felicitous constitutional inventions of this century". Lord Robbins was unconvinced by the explanation that the Comptroller would not be concerned with academic matters; "I personally find it extremely difficult to believe that, with the best will in the world, the Comptroller and Auditor-General could avoid becoming involved in judgments of value and questions of policy if he were to undertake this particular function". This difficulty was returned to when Sir John Wolfenden gave further evidence, with several members of the U.G.C. "I find it difficult, as many of your other witnesses have found it difficult, to see how, if one investigates methodology, one can refrain from, perhaps, calling into question some of the decisions based on that methodology".

The last to give evidence was Sir Herbert Andrew, Permanent Under-Secretary of State at the D.E.S. He, too, thought it would be difficult for the Comptroller to avoid treading on academic toes. "It does seem to me that sooner or later questions would arise that would throw doubt on or put into question the allocations which the U.G.C. had made." Sir Herbert felt that any change might affect the standing of the U.G.C., and that the universities would become concerned if the position of the U.G.C. as a buffer were seen to move. Sir Herbert thought that the relation between the U.G.C. and the D.E.S. would have to be worked out again, which would be difficult, although perhaps not impossible. An audit would, he said, "make it a little bit easier for any government that was minded to extend control over the universities to do it". On the other hand, he thought that refusal to let the Comptroller and Auditor-General look at the books would hardly constitute a serious obstacle to any government that was so minded.

# Melting at High Pressures

by

J. S. ROWLINSON

Department of Chemical Engineering and  
Chemical Technology, Imperial College  
of Science and Technology,  
London, S.W.7

There has been a flurry of speculation about the variation of melting pressure with temperature in the past few years. There are obvious limits to the extrapolation of familiar equations, particularly at high pressures. Model calculations have thrown light on some parts of the problem.

THE shape of the melting curve—that is, of the melting pressure as a function of temperature—for a metal or a molecular crystal has long been the subject of speculation. Gas-liquid curves end in critical points at quite moderate pressures, usually below 100 bar, but there is still some doubt about the fate of the solid-fluid curve. It has been followed experimentally up to pressures of the order of 50 kbar for many metals.

The discussion of these curves is hampered by the absence of an adequate theory of phase transitions. There has, however, recently been a spate of new proposals, and discussion of old proposals, for the representation of such curves. Some of these are related to the hypotheses of Lindemann and Grüneisen, and some are based on computer calculations of melting in model assemblies of hard spheres.

Three old approximations, all of uncertain validity, are widely used in the discussion of the properties of solids. Briefly, they are: (1) Grüneisen's hypothesis that the frequency spectrum of a solid (and in particular the temperature  $\Theta$  used to characterize it) is a function only of the volume. Grüneisen's constant  $\gamma$  is defined by the equation

$$\frac{d \ln \Theta}{d \ln V} = -\gamma \quad (1)$$

(2) Lindemann's proposal that a crystal melts when the molecular vibrations reach a certain amplitude. This has led to a relation between the melting temperature  $T_m$  at an arbitrary pressure, the relative molar mass  $M$ , and the molar volume  $V$ :

$$T_m = CM \Theta^2 V^{(2/3)} \quad (2)$$

The constant  $C$  should be the same for all substances.

(3) Simon's equation for the effect of the pressure on  $T_m$  is

$$\frac{p_m}{a} = \left( \frac{T_m}{T_0} \right)^c - 1 \quad (3)$$

where  $T_0$  is the melting temperature at  $p_m = 0$ , and  $a$  and  $c$  are parameters peculiar to each substance. The equation is useful only for those substances—the great majority—for which  $T_m$  rises monotonically with  $p_m$ .

Salter<sup>1</sup> showed that (1) and (2), with few additional assumptions, led to (3), and that the parameter  $c$  of Simon's equation is related to Grüneisen's constant by

$$c = \left( \gamma + \frac{1}{6} \right) \left( \gamma - \frac{1}{3} \right)^{-1} \quad (4)$$

Kraut and Kennedy<sup>2</sup> recently proposed as an alternative to (3) the equation

$$T_m = T_0 \left( 1 + k \frac{|\Delta V|}{V_0} \right) \quad (5)$$

where  $|\Delta V|$  is the decrease in volume on isothermal compression at  $T = T_0$  to the pressure  $p_m$  that corresponds

to  $T_m$ . At a meeting of the American Geophysical Union in April 1966, Kennedy<sup>3</sup> claimed that (5) held for fifty elements and compounds. Among these are alkali metals for which  $|\Delta V|/V_0$  is about 0.5 at 50 kbar.

This proposal has led to a "flurry of re-examinations"<sup>4</sup>, in which it has been shown independently by Gilvarry<sup>5</sup> and by Vaidya and Gopal<sup>6</sup> that (5) is also closely related to (1) and (2). Equation (5) is obtained by differentiating (2) with respect to volume, using (1) to obtain the volume dependence of  $\Theta$ , and then making a binomial expansion. Hence  $k$  of (5) should also be related to  $\gamma$ , and so to  $c$ , by the equation

$$k = 2 \left( \gamma - \frac{1}{3} \right) = (c - 1)^{-1} \quad (6)$$

In view of the known faults of (1) and (2), it is not surprising that experiment does not confirm the consistency checks (4) and (6). Moreover, these were derived for small values of  $\Delta V$  and  $\Delta T = T_m - T_0$ , while (3) and (5) are used over wide ranges of those variables. Sodium is a metal for which both (3) and (5) represent the melting curve tolerably well, but for which  $c$  is not related to  $\gamma$  or to  $k$  by (6). In contrast, argon is a typical molecular crystal whose melting curve is well represented by (3), and for which the derived value of  $c$  is reasonably close to that found from (4). Even so, (5) cannot be used for argon because of its great initial compressibility. The apparent value of  $k$  for small values of  $\Delta V$  and  $\Delta T$  is about 5 (which disagrees with that obtained from  $\gamma$ ) and this coefficient rises rapidly with increasing pressure. Babb<sup>4</sup> has shown that nitrogen also does not conform to (5).

These comparisons are set out in Table 1, in which much of the uncertainty comes from the failure of Grüneisen's hypothesis and so from uncertainty in the values obtained for  $\gamma$  from the mechanical and thermal properties of the crystal.

Table 1

Substance	$\gamma(\text{obs})^*$	$c(\text{obs})$	$c(\text{from } \gamma)$	$k(\text{obs})$	$k(\text{from } \gamma)$
Sodium	1.18-1.25	3.5†	1.6	1.65†	1.7-1.8
Argon	1.8-2.2	1.5-1.6‡	1.3	(5)§	3.0-3.8

\* From properties of crystal, see ref. 6 for sodium and ref. 7 for argon.

† See ref. 2.

‡ See refs. 8 and 9.

§ See text.

It is hard to say which equation—(3) or (5)—is more likely to be correct in predicting the course of a melting line at very high pressures. Neither has a proper theoretical basis, and the checks provided by (4) and (6) are unreliable guides to their parameters. Moreover, the difference between them can be great when long extrapolations are made. Kennedy<sup>3</sup> has said that at 3 Mbar, the probable pressure at the junction of the inner and outer cores of the Earth, equation (3) leads to a melting temperature of  $\gamma$ -iron of 7,500° C while (5) suggests that it is only 3,700° C.

In the past, some bad extrapolations have been made by using Simon's equation, chiefly because any one set of

results can often be fitted with different pairs of the parameters  $a$  and  $c$ . Nevertheless, the equation has no obvious faults of form and clearly allows both  $p_m$  and  $T_m$  to be unbounded.

The extrapolation of (5) is, at first sight, more attractive since there is only one parameter to be chosen. As Ross and Alder<sup>10</sup> observe, however, the equation must ultimately fail because  $T_m$  is bounded,  $T_m < (1+k)T_0$ . For sodium, which melts at 98° C at zero pressure, this limit is 710° C, which seems most improbable. It is true that some metals—for example, caesium—have maximum temperatures in their melting curves, but it is believed that in all such cases there is a phase transition to a more dense solid at higher pressures, and that this solid then melts along a curve for which  $T_m$  rises monotonically with  $p_m$ .

We can say more about the ultimate behaviour of melting curves by appealing to computer calculations on model assemblies of hard spheres<sup>11</sup>. These show that there is a phase change to a solid structure at values of  $p_m$  and  $T_m$  related by

$$p_m b / RT_m = 18 \pm 1 \quad (7)$$

where the co-volume  $b$  is four times the volume of the spheres. The changes in volume and entropy on melting are independent of  $T_m$ , and therefore  $p_m$  and  $T_m$  are proportional to each other. If real molecules have "hard cores", then this result implies that there cannot be a solid-fluid critical point.

The results for this model can be extended to more realistic models in two ways. Longuet-Higgins and Widom<sup>12</sup> considered an array of hard spheres moving in a uniform negative potential chosen to represent the mean intermolecular configurational energy. This potential raises the melting temperature at  $p_m \sim 0$  from absolute zero, in (7), to a triple-point temperature,  $T_0$ , where

$$RT_0 = -(0.068)U_s(V_s/V_*) \quad (8)$$

where  $U_s$  and  $V_s$  are the molar energy and volume of the solid at  $T_0$ , and  $V_*$  is the molar volume of a close-packed array. If one considers the melting curve in the form of  $\ln p_m$  as a function of  $\ln T_m$ , then this model predicts a line that rises steeply from the triple point to a pressure of the order of  $(-U_s/V_s)$  or 2.8 kbar, where it slowly bends over and then rises more gently, becoming asymptotic to (7) with a slope of unity. The pressure  $(-U_s/V_s)$  plays the same part here as the internal pressure  $\alpha$  in Simon's equation, which is about 2.3 kbar for argon<sup>7,9</sup>. This shape of melting curve, with two different logarithmic slopes above and below the internal pressure respectively, is a good representation of the melting curves of the inert gases<sup>13</sup> and the turning point marks the change from the

region where the crystal is held together by its attractive forces (at low  $p_m$ ) to that (at high  $p_m$ ) where its stability is due primarily to the higher packing density of an ordered array, that is, to the effects of the repulsive part of the intermolecular potential.

At very high pressures the representation of molecules by hard spheres over-estimates the volume they occupy. If, more realistically, the pair potential  $u(r)$  is taken to be proportional to  $r^{-n}$  then  $p_m$  is proportional to a power of

$$T_m \text{ of } \left(1 + \frac{3}{n}\right). \text{ This follows directly}^{13} \text{ from the fact that}$$

the intermolecular virial function of such an assembly is a direct multiple of its intermolecular energy. Hence the limiting form of  $c$  of Simon's equation becomes

$$c = 1 + \frac{3}{n} \quad (9)$$

This equation was obtained for a more restricted model by Domb<sup>14</sup> some years ago.

This extension of the hard sphere results is not restricted to the potential proportional to  $r^{-n}$ , but may be made although with less simple results for any arbitrary but steep potential<sup>13</sup> by means of a Taylor expansion in a parameter that is the reciprocal of a measure of the steepness—for example  $n^{-1}$ . This leads again for all sufficiently steep potentials to a limiting behaviour similar to that of (7) but with a logarithmic slope greater than unity, to a volume change on melting that is non-zero at all finite temperatures, and so to the absence of a solid-fluid critical point or of a change to a transition of higher order.

What is still uncertain is the degree of steepness of the potential required for these extensions of the hard-sphere model to be valid. Since the partition function depends on an exponential function of the configurational energy, then a necessary condition is presumably that all derivatives of  $\exp[-u(r)/kT]$  vanish at  $r=0$ . But this is probably too weak to be a sufficient condition.

## Intelligence among University Scientists

by

JOHN GIBSON  
PHYLLIS LIGHT

Department of Genetics,  
University of Cambridge

Studies on the deviation IQ of scientists at the University of Cambridge show that there is a considerable variation among scientists. However, IQ seems not to be related to success as a scientist, provided that it is greater than a certain threshold which varies according to the particular scientific discipline.

IN an investigation concerned with fertility and social mobility, the test known as the Wechsler Adult Intelligence Scale (W.A.I.S.)<sup>1</sup> was given to one hundred and forty-eight scientists in the University of Cambridge. The scientists were sampled from the thirty-three "science" departments in the University. The Department of

Geography, the Faculty of Economics and Politics and the Farm Economics Branch of the Faculty of Agriculture were included in the sample although they would not be considered as science departments in some universities. The chief sciences represented in the sample are indicated in Table 1.

Fig. 1.

The initial sample comprised all the male teaching officers and holders of posts in science departments at June 1, 1965, who were born on or after January 1, 1931. The age range was 25 to 34 years. The total number of scientists meeting these requirements was one hundred and eighty-five—of these, fifteen did not agree to co-operate and thirteen were either abroad or could not be located during the investigation. A further nine members of the sample were already familiar with the W.A.I.S. and were not tested, although in some cases their scores were known; such scores are not included in the data.

### Sample

The age range of this sample, which consisted of 80 per cent of the possible sample, is completely encompassed by one of the standardized W.A.I.S. age ranges. No correction for age was therefore necessary to obtain the deviation IQ scores shown in Fig. 1.

Table 1

Subject of bachelor degree	n	Mean deviation IQs	Range of scores	Variance	Standard deviation of the mean
Agricultural sciences	17	121.6	110-135	41.18	1.55
Biochemistry	10	130.0	122-141	41.33	2.034
Biological sciences	20	126.1	113-135	27.05	1.15
Chemistry	12	129.6	121-138	30.45	1.59
Engineering sciences	16	125.0	111-138	57.46	1.9
Mathematics	16	130.4	124-136	16.0	1.0
Medical sciences	10	127.0	116-134	46.22	2.15
Physics	20	127.7	112-136	39.05	1.4
Social sciences	10	121.8	112-132	41.55	2.04

The scores range from 110 to 141 with a mean of 126.5 and a standard deviation of 6.3 IQ points. All the scores fall within three standard deviations of the mean. The distribution of the scores in terms of Wechsler's classification<sup>1</sup> shows that all the scientists obtained scores above the seventieth percentile rank for the general population—35.2 per cent are classified as "very superior", 51.3 per

cent as "superior", and 13.5 per cent as "bright normal". Approximate percentages of these three groups in a general population sample are 2.2, 6.7 and 16.1 respectively. For any age group in the general population the distribution of W.A.I.S. deviation IQ has a mean of 100 and a standard deviation of 15, the middle 50 per cent of each age group having IQs between 90 and 110. Thus, for this sample of scientists, the range of IQs are similar to the range of scores expected of the higher 25 per cent of a representative general population sample.

The scientists were classified into groups based on the principal subject of the bachelor degree. Fifteen scientists, including those who read geography, geology and metallurgy, were not represented by sufficient numbers to be considered separately and are not included in any of the subject groups. The nine subject groups which could be compared are listed in Table 1. These groupings do not correspond to university departments.

Scientists who had specialized in mathematics for the bachelor degree obtained the highest mean deviation IQ in the sample. The variance for the mathematicians' scores was significantly lower than the variances for the scores obtained by engineering scientists, medical scientists and physicists ( $0.05 > p > 0.01$ ). The scores of the engineering scientists had the highest variance of IQ scores.

### Significant

The significance levels for each of the thirty-six comparisons of mean IQ scores which can be made between the nine groups are given in Table 2. Medical scientists did not differ significantly from any of the groups in mean IQ scores. The mathematicians had significantly higher mean scores than four of the groups, the social scientists had significantly lower mean scores than four of the groups and the agricultural scientists had lower scores than five of the groups.

The deviation IQ scores of 146 scientists could be related to the class of the bachelor degree (Table 3). The regression coefficient of IQ on degree class was small ( $r = +0.15$ ) and non-significant ( $p > 0.3$ ). In the present sample

Table 2. COMPARISON OF THE MEAN IQ SCORES OF THE NINE SUBJECT GROUPS

Subject of bachelor degree	Mean IQ	2 Bioch.	3 Chem.	4 Phys.	5 Med.	6 Biol.	7 Eng.	8 Sociol.	9 Agric.
1 Mathematics	130.4	—	—	—	—	+	+	++	++
2 Biochemistry	130.0	—	—	—	—	—	—	++	++
3 Chemistry	129.6	—	—	—	—	—	—	++	++
4 Physics	127.7	—	—	—	—	—	—	++	++
5 Medical sciences	127.0	—	—	—	—	—	—	—	—
6 Biological sciences	126.1	—	—	—	—	—	—	—	++
7 Engineering sciences	125.0	—	—	—	—	—	—	—	—
8 Social sciences	121.8	—	—	—	—	—	—	—	—
9 Agricultural sciences	121.6	—	—	—	—	—	—	—	—

Probabilities. \* < 0.001; + < 0.01; ++ < 0.05; --- > 0.05.

Table 3a

Class of bachelor degree	n	Mean IQ score	Variance
First class	77	127.5	40.85
Upper second	36	126.8	35.36
Lower second	17	124.4	40.25
* Others	16	122.2	29.0

\* Includes third class and pass degrees.

Table 3b

Table 3b. PROBABILITY LEVELS OF "t" IN COMPARISONS OF MEAN IQ SCORES FOR DEGREE CLASS

Degree classes	2:1	2:2	Others
1	>0.5	<0.05	<0.001
2:1		>0.1	<0.01
2:2			>0.3

scientists who had gained first and upper second class degrees had significantly higher mean IQ scores than those with lower degrees ( $p < 0.01$ ) although the variances were not significantly different. It is interesting that both the highest and lowest individual IQ scores were found among scientists with first class degrees. This relationship between the class of the bachelor degree and IQ is in part reflected in the differences in mean IQ scores between the subject groups described here. The proportions of the different degree classes were not similar in all the nine subject groups (Table 4).

Table 4. PROPORTIONS OF VARIOUS DEGREE CLASSES IN SUBJECT GROUPS

Subject of bachelor degree	Degree class			Others
	1	2:1	2:2	
Agricultural sciences	4	3	2	8
Biochemistry	6	3	1	—
Biological sciences	10	8	2	—
Chemistry	7	4	—	1
Engineering sciences	8	3	2	3
Mathematics	13	2	—	1
Medical sciences	5	1	2	1
Physics	9	8	3	—
Social sciences	5	2	2	1

The present IQ data can be compared with Mackinnon's findings<sup>2</sup>, using Terman's Concept Mastery intelligence test on samples of distinguished American scientists, and with Hudson's findings<sup>3</sup> using the A.H.5 intelligence test on English sixth formers. Each of these studies indicates that above a certain threshold level (in the region of IQ 110) a conventional intelligence test measures qualities unrelated to the success of an individual in a scientific career. The present data support the suggestion that there may be a threshold level of IQ below which an individual is unlikely to become a scientist. Whatever qualities are measured in the W.A.I.S. test, however, they are not equally represented in each of the nine subject groups in the present sample and thus the level of the IQ scores may be relevant in some scientific subjects. The biochemists, chemists and mathematicians all had IQs above 120, while some scientists in the other groups had IQs below 120.

The significant finding in the present study is the large proportion of scientists in all subjects with IQ scores below 130 (Fig. 1). Whether those with higher scores enjoy more success in a particular scientific subject is not known and to generalize from the present data would be as misleading as the statement often made that all scientists have high IQs.

We thank all the scientists in the sample (and others) who generously helped in this work. One of us (J. G.) acknowledges the financial support of the Eugenics Society (London) and the Hopkins Donation Funds (U.S.A.).

## BOOK REVIEWS

### OLD MASTER

#### Collected Papers of G. H. Hardy

Including joint papers with J. E. Littlewood and others. Vol. 1. Edited by a committee appointed by the London Mathematical Society. Pp. 700. (Oxford: Clarendon Press; London: Oxford University Press, 1966.) 105s. net.

G. H. HARDY was the author or part author of more than three hundred original papers and several influential books. His work had a profound influence throughout the whole of analysis and, more than any other mathematician, he was responsible for the renewal of interest in "real" mathematics in Britain. The London Mathematical Society intends to publish all Hardy's papers, including those written in his very fruitful collaboration with Littlewood and Ramanujan, and this handsomely produced volume is the first of seven. The papers are arranged in groups according to subjects; this volume contains those on Diophantine approximation and additive number theory.

The work of Hardy and Littlewood on Diophantine approximation arose primarily out of their interest in problems on uniform distribution modulo 1. Let  $f(n)$  be a function defined on the positive integers and write  $(f(n))$  for the positive fractional part of  $f(n)$ —that is, for the "decimal part" of  $f(n)$ . Then the problem of uniform distribution is that of finding conditions on  $f$  so that the frequency with which the values of  $(f(n))$  fall in any sub-interval of the interval (0,1) is proportional to the length of the sub-interval. This problem is closely related to that of estimating the sums

$$\sum_{n=1}^N e^{2\pi i f(n)} \quad \text{and} \quad \sum_{n=1}^N [(f(n)) - \frac{1}{2}]$$

In its turn, the latter sum is related to the problem of finding the number of points with integral co-ordinates in a given right-angled triangle.

Hardy and Littlewood developed a method, now known as "the Hardy-Littlewood method", which provides a general line of attack on all problems concerned with finding the number of ways in which a given number can be expressed as a sum of numbers of certain special types. There is, for example, the problem of representing a number,  $n$ , as the sum of  $s$  squares. If  $r_s(n)$  denotes this number, then  $r_s(n)$  is the coefficient of  $q^n$  in the expansion in powers of  $q$  of  $(1 + 2q + 2q^4 + 2q^9 + \dots)^s$ . One takes  $q = e^{2\pi i \tau}$  and then the problem of picking out  $r_s(n)$  becomes a problem of the behaviour of the resulting function of  $\tau$ . Similar arguments can be used to investigate the problem of representing  $n$  as a sum of  $k$ th powers (Waring's problem) and the problem of finding the number of ways in which  $n$  can be expressed as a sum of smaller numbers (the problem of partitions). Another variant of the method can be used to attack the celebrated conjecture of Goldbach, which asserts that every even number from 6 onwards is the sum of two primes other than 2. If this is true—it is still unproved—then every number greater than 5 is the sum of three primes and, using their analytical method, Hardy and Littlewood were able to prove that this result is true for all sufficiently large numbers. To do this they had to make an assumption about the zeros of a certain function—an assumption which is still unproved. (On the other hand, Vinogradov

has proved the three primes theorem without this assumption.)

Each group of problems in the *Collected Papers* has a lucid introduction and commentaries on subsequent developments and unsolved problems. The papers themselves make absorbing reading—I am ashamed to admit that I was reading many of them for the first time—and reflect the extremes of creativity and technical facility which were characteristic of the authors. One is impressed, too, by the elegance of the style. It is not inappropriate to compare it with accounts given in *Wisden* of the cricket of the day; both present us with glimpses of a more generous age.

J. V. ARMITAGE

## THE THYMUS

### The Thymus

Experimental and Clinical Studies. Edited by G. E. W. Wolstenholme and Ruth Porter. (Ciba Foundation Symposium.) Pp. xiii+538. (London: J. and A. Churchill, Ltd., 1966.) 80s.

THE true nature of thymic function has always been one of the most intriguing mysteries in biology. Suggested roles have ranged from the filling of the thorax during contraction of the lung to the elaboration of a fluid to attenuate the blood, and apart from one or two notable contributions to our knowledge during the first fifty years of this century, there has been very little evidence on which to base better theories. The deficiencies are now being made good and a wealth of information has been collected, particularly in the past five years.

In this volume are some twenty contributions covering a fairly wide range of processes in which the thymus appears to play a leading part. The papers were read at the meeting arranged in Melbourne in August 1965, in honour of Sir Macfarlane Burnet on his retirement as director of the Walter and Eliza Hall Institute of Medical Research. Fittingly, all the contributions are of a high standard, and from them and the discussions which follow a very comprehensive survey emerges of what is known about the gland and of the present trends of thought preoccupying those who are actively engaged in research.

During the past few years, following the work of J. F. A. P. Miller, attention has been focused mainly on the role of the thymus in immunity and on the associated—indeed inseparable—problem of the origin, function and fate of the lymphocyte. Miller's own contribution to the symposium emphasizes the central part which the thymus plays in the development of immunological capacity and suggests that the chief functions may be the provision of lymphocytes or precursor cells and the elaboration of a factor which induces competence. Supporting evidence for thymic hormone production is provided by the electron microscope studies of S. L. Clark, but D. Metcalf provides convincing evidence against any massive migration of thymic lymphocytes to peripheral lymphoid tissues as was previously thought to occur. Elegant experiments by J. L. Gowans and his co-workers demonstrate the close association between antibody production by lymphocytes and the mode of presentation of the antigen. The macrophage may be an essential intermediary in the inductive process. An important theme which emerges from this and from other work, including that of Auerbach on embryogenesis of thymus and lymphocytes, is the possibility of the existence of two functionally and developmentally separate systems of cells, one responsible for antibody formation and the other for the mediation of transplantation reactions. As yet, the only direct experimental evidence for the existence of two such systems derives from work on the bursa of Fabricius of chickens. There have been reports, however, post-dating the Melbourne meeting, of the ability of neonatally thymectomized animals to produce antibody

to certain antigens, and in this volume Professor Good directs attention to the same kind of dissociation found in man.

Other contributions deal with the relationship between the thymus and tolerance, the competence of cloned cell populations and with the thymus in ontogeny and phylogeny. Sir Macfarlane Burnet describes some of his own observations on mast cell metaplasia in the thymus, and some of the work done on the relationship of the gland to the auto-immune haemolytic disease of the NZB strain of mice is also presented.

With the increasing awareness of the importance of the thymus in immunobiology, there has been a re-awakening of interest in the pathology of the human thymus and in the association between it and immunological deficiency syndromes and auto-immune disease. These topics are dealt with in a number of interesting papers. The lecture given by Dameshek is particularly stimulating.

In any symposium, as in any single paper, only a few aspects of a topic can be touched on. It is out of the question, therefore, to lament the absence of reports dealing with the other myriad facets of thymic function. In any event, the recorded discussions between members of the symposium cover such a wide field that almost all the related problems are included. Indeed, the sections devoted to discussions form the most valuable part of the whole volume. It remains true, however, that although better theories of thymic function have now been formulated, they still do not fit all the known facts. It is to be hoped that the next few years will see further dramatic advances in our knowledge, and perhaps the answer to the problems of human auto-immune disease.

R. MAWDSLEY

## THE FUNGUS SPORE

### The Fungus Spore

Edited by M. F. Madelin. (Proceedings of the 18th Symposium of the Colston Research Society, held in the University of Bristol, March 28–April 1, 1966.) Pp. xvi+338. (London: Butterworth and Co. (Publishers), Ltd., 1966.) 120s.

THE spore represents in some respects the most significant part of the life cycle of a fungus, and as such is of interest to all mycologists. This volume, therefore, in bringing together up-to-date information on many facets of spore behaviour, is a welcome addition to the mycological literature.

It comprises a series of authoritative papers from a symposium held at the University of Bristol, and the organizers are to be congratulated on the balance that has been attained between the diverse aspects of the main subject. The initial stages of the meeting were concerned with the process of spore production as observed in the main systematic groups. This topic, together with the associated one of spore structure, was enlivened by the prominence given to studies pursued with the aid of the electron microscope. A stimulating account of spore liberation by Professor C. T. Ingold introduced that part of the symposium devoted to spore dispersal and germination, and the latter aspect in particular received excellent coverage. Professor L. E. Hawker describes the "morphological and anatomical changes" that can be observed during germination, while Professors V. W. Cochrane and D. Gottlieb elucidate so far as is possible the associated biochemical metabolism. Some of the factors influencing spore germination were also discussed at some length, although perhaps a more ecological bias to this interesting subject would have been more rewarding. The concluding papers considered the part played by spores in the epidemiology of plant and animal diseases.

The compilation of these papers has, therefore, the essential ingredients of a first class reference book—

authority and a wide range of discussion around the main theme. The material is well presented and adequately illustrated, and the various authors have interpolated sufficient pertinent speculation both about future lines of investigation and the interpretation of present results to sustain interest through some of the more involved passages. It is guaranteed a wide readership and, although an expensive publication, is a worthy accession to any library.

R. K. ROBINSON

## RUSSIAN FORESTS

### The Forests of the U.S.S.R.

By V. P. Tseplyaev. Translated from the Russian by A. Gourevitch. Pp. v+521. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1965.) 138s.

A GENERAL introductory chapter covers the classification and general features of the forests of the Soviet Union, and is followed by a short survey of forest distribution, by area, in the several republics of the Soviet Union. An account of forest zonation is given in the third chapter and this is followed by the principal parts of the book—two chapters descriptive of the different types of forests in the Soviet Union. One chapter covers coniferous and the other broad-leaved forests. Forests are dealt with according to the predominant type of tree—pine, fir, larch, oak, for example—so that mixed forests may be found under more than one heading. The more important or extensive types of forest are further subdivided geographically. For each of them there is a short history and account of forest husbandry and exploitation, a brief descriptive account of forest physiognomy, flora and fauna, an indication of quality of the stands, a survey of regeneration, and a statistical survey of forest area, age characteristics, reserves, usage and increment. Much of the information throughout the book is presented in tabular form. There are also short chapters surveying forest utilization in the Soviet Union and the forest resources of the world (based on the FAO survey of 1953).

The comparative vastness of the forest resources of the Soviet Union is clearly apparent from this book, but it is also clear that this vastness has not blinded Russian foresters to the need to conserve, maintain and properly exploit their forests. It is also evident that there are large areas of the Soviet Union, especially in the drier parts of the Middle Asian republics, where forest resources are negligible and conditions for silviculture difficult. Other areas in the south, such as Dagestan, have clearly suffered and still suffer from the bad effects of over-exploitation, over-grazing and neglect. Russian foresters are also fully aware of the amenity value of forests, particularly in the vicinity of large centres of population. An account of the forests of the Moscow "green belt" is of interest to all who are concerned with the wellbeing of city surroundings.

The English translation reads well and is remarkably free from errors of usage and spelling. It should, however, be noted that "cedar" is used to cover certain *Pinus* species, not *Cedrus*, while "aspen" includes more than the one species *Populus tremula*. A few explanatory notes have been added where necessary, but they do not intrude on the original text. In dealing with official Russian names of organizations and institutes, a happy balance has been struck between translation and transliteration.

Throughout the book there are useful references to forest husbandry and recommended practice in the various forest types and regions of the Soviet Union, but the book is in no way a forestry handbook but rather a source-book or compendium of the forest resources of the Soviet Union in the period 1957–59. For a book of this kind, it is remarkably readable—a reflexion of the love of

forests of the original author as well as of the skill of the translator.

C. JEFFREY

## NOBEL SYMPOSIUM

### Muscular Afferents and Motor Control

Edited by Ragnar Granit. (Proceedings of the First Nobel Symposium held in June 1965 at Södergarn, Lidingö, County of Stockholm.) Pp. 466. (New York and London: John Wiley and Sons; Stockholm: Almqvist and Wiksell, 1966.) 150s.

THIS record of the first Nobel symposium contains some 450 pages of scientific papers in 39 separate contributions by 61 authors, most of whom were present at the discussions. We are told in the preface that "it was decided not to publish the lively discussions that took place, unless the discussants themselves wanted it and were prepared to deliver signed contributions". Regrettably for those who set a high value on this form of thinking aloud, very few of the participants delivered their signed contributions, so that only six pages of the volume are given over to discussion. It would, of course, have greatly lengthened the book had discussion been included and perhaps the task of collation and publication would have been exceedingly difficult. The reader is bound to be curious, however, as to what was actually said in discussion of many of the arguable and open statements in these papers.

The inaugural paper by Lord Adrian stresses the importance of this Nobel Foundation experiment in a new technique. He says "Scientists, therefore, are learning how to profit by the classical method, the symposium of experts, few enough to sit round a room, with a definite subject on their agenda and a chairman . . . like Socrates . . . to keep them to the point", and later "... we hope to go home with clearer ideas about the nervous apparatus which regulates muscular contraction so that movements are smooth and posture is adjusted to suit them. The subject is ripe for discussion". But the general reader of this important volume has been prevented from sharing those clearer ideas about nervous action contributed to the discussion. By the publication of the Proceedings of this first Nobel symposium in the present form he is scarcely better off than if the papers had been published without the contributors ever having visited Stockholm.

It is scarcely possible to summarize or even to review the contents of the volume, dealing as it does with nearly forty topics within the very wide scope of its title, from the structural aspects of mammalian muscle spindles through the analysis of their responses to the peripheral and central mechanisms of control of motor systems in man and the cat. It is obvious, however, that this collection of papers will form a valuable source of reference on the sensory apparatus of muscle and the control of motor function. It will particularly serve the needs of those bio-cyberneticians interested in developing theoretical concepts about central nervous activity and the theory of action of the neuro-musculature. In it they will find many suggestions and ideas about possible mechanisms for regulation and control in the central and peripheral nervous and motor systems.

One of the difficulties in writing meaningful accounts of experimental work in neuro-physiology is the vast amount of detail that must be put on record in any statement of results, if the statement is to have any value at all either in its own right or in comparison with other work. The problem is made more difficult by differences over nomenclature. It is especially to be regretted that the final day's discussion on this topic has not been reported.

The difficulty of complexity can be overcome in two ways—by well formulated theory and more research

aimed at deciding critical issues raised by the theory. An urgent need, as judged by the absence of mathematical papers in this symposium, is for the formulation of theories of nervous action based on relatively simple models which can be tested by experiment and by computer.

W. F. FLOYD

## MOISTURE MEASUREMENT

### Humidity and Moisture

Measurement and Control in Science and Industry. Editor-in-Chief: Arnold Wexler. Vol. 1: Principles and Methods of Measuring Humidity in Gases. Edited by Robert E. Ruskin. Pp. xv + 687. \$30. Vol. 2: Measurement and Control in Science and Industry. Pp. xv + 634. \$27.50. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1965.)

EACH of these volumes is a collection of papers presented, under the sponsorship of the National Bureau of Standards and other United States interested organizations, in May 1963 at an International Symposium on Humidity and Moisture in Washington. Their appearance reflects the extraordinary change which has taken place in recent years in what had previously been one of the most neglected fields of physics. The subject of hygrometry rarely merits more than a paragraph or two in text-books of physics, and most science students meet it as a single unpleasant and unrewarding experiment in elementary physics. This state of affairs is all the more inexplicable when the industrial importance of humidity and its control is borne in mind. The change has been brought about (and this is obvious from the subject matter of these volumes) principally by two factors.

The first is the increase in knowledge of the principles of automation, which has made it attractive to develop humidity sensors that can be suitably matched into servo-systems. The huge domestic market for air conditioning appliances in the U.S.A. promises adequate reward for successful solutions. The second is the need voiced by the armed services and by space agencies for successful methods of humidity measurement and control.

It is no surprise, therefore, that of the sixty-eight papers in Volume 1, no fewer than fifty-one originate in the United States or Canada; in Volume 2 the proportion is sixty-nine out of a total of seventy-four.

Volume 1 begins with an excellent review of the underlying theory, and the tables and charts and other computational aids used with that commonest of all hygrometers, the wet- and dry-bulb instrument. The remaining papers deal with various forms of this instrument, with dew-point, electric, spectroscopic and coulometric hygrometers, and finally with a number of miscellaneous methods which cannot be classified under the foregoing heads. The dew-point hygrometer has obviously become a much more attractive instrument following on the invention of Peltier electric cooling elements. It is interesting to find that the oldest and simplest hygrometer of all, the hair hygrometer, still has its uses.

The second volume is concerned with the applications of humidity measurement and control in various fields of interest. These cover biology and medicine, agriculture, controlled humidity chambers, air conditioning systems, process control, meteorology, radio propagation and atmospheric refraction. The range of the volume indicates the general importance of the subject.

In a publication of this type and especially in the second volume, involving so many separate contributions, it cannot be expected that all are of the same standard. The general level is high, however, and the quality of presentation is of an excellence one would expect of a publication sponsored by the National Bureau of Standards. The index to Volume 1 is adequate, but that to Volume 2 is so terse as to be hardly of use. These two

volumes, comprising a collection of papers representative of the present state of the art, can be recommended to all interested in hygrometry, with the usual regret that few individuals outside North America will be able to afford them.

W. H. J. CHILDS

## COMMITTEE BOOK

### History of Mankind

Cultural and Scientific Development. By Caroline F. Ware, K. M. Panikkar and J. M. Romein. Vol. 6: The Twentieth Century. Part 1: Introduction: The Development and Application of Scientific Knowledge. Pp. xlvii + 1-646 + plates 1-20. Parts 2-4: The Transformations of Societies; The Self-Image and Aspirations of the Peoples of the World; Expression. Pp. xiii + 647-1387 + plates 21-64. (London: George Allen and Unwin, Ltd., 1966. Published for the International Commission for a History of the Scientific and Cultural Development of Mankind.) 168s. net.

THIS instalment in Unesco's six volume *History of Mankind* is a vivid proof that committees cannot write books. The project is organized "under the mandate of the International Commission for a History of the Scientific and Cultural Development of Mankind", and the volume on the twentieth century (published in two volumes) has been written by a team of named authors working under the supervision of an author-editor and two co-author-editors. A part of the exercise, which began in 1954, has required that authors should win the agreement or at least invite the dissent of a number of distinguished reviewers. The result, in many chapters, is that the footnotes which say who disagrees with whom are frequently more interesting than the necessarily pallid chapters which they accompany.

Dr. J. Bronowski, who contributed the chapter on "The New Scientific Thought", seems to have had a particularly rough ride. Dutifully, and with commendable brevity, he gives a straightforward Darwinian explanation of the principle of natural selection, only to earn for his pains the rebuke from Academician Ivan Malek that "the principle of natural selection is explained incorrectly, in a Malthusian fashion. . . . Darwin was mistaken in making use of Malthusian ideas and referring to them, but this does not detract from the essential correctness of Darwin's teaching on natural selection". Academician Malek goes on to explain precisely what he means, and the author-editors rally to the defence of their contributor by calling "attention to the fact that the explanation presented in the text is that given by Darwin". But this is only a beginning. Poor Bronowski is taken to task for what he says about Marx and Engels, for allegedly failing to distinguish between "mechanistic determinism and determinism as such", for his espousal of the positivist interpretation of quantum mechanics, and for many other misdemeanours as well. It is all good knockabout stuff, and no doubt faithfully representative of many Unesco meetings. But is it the history of mankind?

JOHN MADDOX

### Catalogue of Meteorites

With special reference to those represented in the collection of the British Museum (Natural History). By Max H. Hey. Third, revised and enlarged, edition. (Publication No. 464.) Pp. lxviii + 637. (London: British Museum (Natural History), 1966.) 120s.

STUDENTS of meteorites in Britain are exceptionally lucky to have the British Museum's large and comprehensive collection of meteorites at their disposal, and to have a tradition of meteorite study behind them which

includes such classic works as Prior's classification of meteorites. Prior also put together the first edition of the *Catalogue of Meteorites* which has now gone into a third edition, enlarged and improved by Dr. M. H. Hey. Apart from the catalogue itself the book has a useful summary of the classes of meteorites and an interesting chapter on the history of the British Museum collection. Also included are catalogues of meteorite craters and of tektites in the British Museum collection. A particularly welcome addition to the volume is the summary of minor element determinations. Clearly a summary of major element determinations as well would involve an enormous amount of research, but perhaps it is not too much to hope that future editions will carry such a summary. However, the book is a mine of information as it stands and will be invaluable to those working in the field.

A. M. MARSHALL

### Lie Groups for Pedestrians

By Harry J. Lipkin. Second edition. Pp. ix+182. (Amsterdam: North-Holland Publishing Company, 1966.) 20 guilders; 40s.

THIS book is written for physicists, and will not satisfy those who seek an understanding of the mathematical properties of Lie groups and Lie algebras. The author assumes a previous familiarity with spin and isospin, with creation and annihilation operators and with other quantum mechanical concepts, and he develops the properties of Lie algebras largely by analogy. The book is suitable for those who seek a superficial understanding of the mathematics; it is not recommended for a serious theoretical student, who should have some understanding of the topological background (especially the idea of compactness), and of the relationship between Lie groups and Lie algebras. For an experimental physicist who simply seeks to understand particle classification schemes on a phenomenological basis, the book provides a painless introduction to the subject, working out details of many of the more familiar classification schemes. The author admits that the book is not comprehensive, and this should be borne in mind by the reader.

J. S. R. CHISHOLM

**Mixed Boundary Value Problems in Potential Theory**  
By Ian N. Sneddon. Pp. viii+283. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, a Division of John Wiley and Sons Inc., 1966.) 40 guilders; 80s.

READERS of this book are impelled along by a number of problems taken from mathematical physics which have the form of boundary value problems of mixed type. Functions, usually harmonic, have to be determined from the specification of the function on parts of the boundary of the domain and of its normal derivative elsewhere on the boundary. There are plane problems and axisymmetric problems including the problems of the charged disk and the charged spherical annulus from electrostatics, punch and crack problems from elastostatics, and slit problems from hydrodynamics. All these are variants on one theme.

Most of the book is devoted to the solution of the harmonic mixed boundary problem by means of dual integral equations and dual series representations. The author is an authority on the subject, and this is reflected in his presentation of the material.

The principal formulae used in the analysis are gathered for easy reference into one chapter, and the basic methods for solving dual integral equations are presented early in the book in connexion with the classical problem of the electrostatic disk.

Most of the dual integral equations studied have Bessel or trigonometrical functions as kernels, whereas the dual series are based on Bessel functions, trigonometrical functions, Legendre polynomials and Jacobi polynomials. Triple integral equations and series representations are

also considered, these arising when different conditions are imposed on three parts of the boundary of the domain.

The power of the methods is evident in the application in Chapter 8 to the electrostatic field effects of electrified disks, strips and spherical caps. Some interesting methods of obtaining bounds to the capacity of condensers formed from circular disks are given here.

This book is to be recommended to all students who wish to become familiar with current methods of research in the title topic.

E. E. JONES

### Theory of Automatic Control

By H. Takai. Translated by Scripta Technica, Ltd. Edited by E. J. Feakes. Pp. ix+315. (London: Iliffe Books, Ltd., 1966.) 75s. net.

CONTROL engineering and control theory have much relevance to other fields, so that it is worthwhile to spread the gospel outside the boundaries to other disciplines. One object, however, to the fact that it is always the same portion of the Bible which the preachers expound.

Nine of the ten chapters in *Theory of Automatic Control*, translated from the Japanese, deal with the well worn topic of continuous linear systems. Some of the standard sub-topics are discussed and treated quite competently as well, but no more thoroughly or more topically than any number of well established texts which already exist in English and which do not need translation. The tenth chapter is entitled "Nonlinear Automatic Control" but, along with a superficial treatment of non-linear systems, it discusses sampled data systems as if the phenomenon of sampling made it fit into this chapter.

In short, the necessity of translating in 1966 this text, published in Japanese in 1961, is not readily obvious.

PAUL ALPER

### The World of Learning

1966-67. Seventeenth edition. Pp. xiv+1578. (London: Europa Publications, Ltd., 1967.) 150s. net

THE seventeenth edition of *The World of Learning* differs from the sixteenth in that it is even larger and contains more detail on universities and academies in a number of countries which were covered only sketchily in the previous volume. The information on the Soviet Union has been expanded, and the learned societies and research institutes of Argentina, Austria, Japan, Mexico and Holland are now classified systematically. One new feature of the book is the additional information on the chief language of instruction where this is not at once obvious, and on the length of the academic year. More than 150 countries are dealt with in more or less detail: their universities and colleges, libraries, museums and art galleries, and their learned societies and research institutes are listed, as are the names of their leading scholars. The book also contains an international section on the aims and functions of Unesco, and on the various world scientific and cultural organizations. Anyone who deals with scientists outside his own country will find this book a valuable guide to the proliferating network of international science.

JOHN SPENCER

## OBITUARIES

### Professor C. F. A. Pantin

CARL FREDERICK ABEL PANTIN, who died on January 14, at the age of 67, made many distinguished contributions to invertebrate physiology.

After Tonbridge and Christ's College, Cambridge, he went to the Marine Biological Laboratory, Plymouth, in 1922, where he investigated the physiology of amoeboid movement. In 1929 he returned to Cambridge as lecturer

and fellow of Trinity College. He was then concerned with the physiology of the crustacean muscular system; he wrote a series of papers on the mechanism of excitation and inhibition. Later he made a very precise investigation of the mode of action of the nerve net and muscular system of Coelenterates, in particular in sea anemones. He discovered that the nerve net will only respond to a series of shocks, each of which elicits a single impulse in the net. Each group of muscles responds to a series of shocks of characteristic number and time interval. This enabled Pantin to explain the mechanism by which the animal's behaviour is controlled. He later investigated the functional anatomy of the nemertines, which were then little known in Britain. During this time he became reader in zoology, and succeeded Sir James Gray as professor in 1959.

Among his many general writings was a paper on identification and recognition, which was a presidential address to the British Association. Pantin was also active in the Royal Society, to which he was elected in 1937, and which awarded him a Royal Medal in 1950; he had been president of the Linnean Society, and in 1963 became chairman of the Trustees of the British Museum (Natural History). He was always interested in marine biology overseas, and was recently a very active chairman of the Nuffield Unit of Tropical Animal Ecology in Uganda. Zoology at Cambridge has benefited much from his great interest and experience in the teaching of science.

#### Professor R. M. Sievert

ROLF MAXIMILIAN SIEVERT died in Stockholm on December 3, aged seventy. He had been director of the Institute of Radiophysics of the Karolinska Institutet since 1937.

When Gösta Forsell, the founder of Swedish radiology, met Sievert, a physicist, in the United States, he persuaded him to start work in radiation physics and build up a hospital organization. In the early twenties hospitals did not standardize the amount of radiation which they administered to patients, and so Sievert and his assistants developed the Sievert condenser chambers to measure dosage. These were soon in use throughout the world. Dosage for the treatment of tumours was based on detailed measurements made on wax phantoms. Sievert was also keenly interested in radiation protection, and this resulted in his work on radiation biology, on which he became an authority.

Sievert realized the importance of international co-operation in the establishment of dose units and protection rules which were generally accepted in all countries. In 1928 he was one of the founders of the International Radiation Protection Committee, and he was later on the United Nations Scientific Commission on Radiological Protection; he was chairman in 1963-66. He was the first member with a natural science degree to be appointed professor of radiation physics at the Karolinska Institutet, which is a medical institute. In 1944 Sievert became a member of the Royal Swedish Academy of Sciences, and in 1959 of the Academy of Engineering Sciences. During the Second World War he had taken the initiative in the formation of a research institute for defence, and he was a member of the board until 1945. His administrative talent was also used in the planning of the Geophysical Research Institute in northern Sweden. His last years were occupied with plans for the National Institute of Radiation Protection, which was ready in 1965. Sievert remained active until the last days before his death, as a chairman of committees, and he continued to take an interest in the work of his institutions.

ARNE FORSSBERG

#### Dr. Paul White

PAUL WHITE, senior lecturer in applied mathematics in the University of Reading, died on January 7, aged sixty-two.

He was born and grew up in Lewisham, where he attended Colfe's Grammar School, and he went to Clare College, Cambridge, in 1922 as an Entrance Scholar. He gained a double first in mathematics and then a first in physics, and went on to undertake research in the Cavendish Laboratory under Lord Rutherford, working on the properties of  $\beta$ -particles and their passage through thin films. A contemporary of this time refers to "a great personal impression of brilliance". After obtaining a Ph.D., he went to Aberdeen as a Carnegie Teaching Fellow, where with G. P. Thomson he continued and extended his work to consider cathode rays.

In 1933 he went to the University of Reading. Work with Crowther and Liebmann on the interaction of X-radiation with biological colloids and on electro-osmotic effects stimulated an interest in statistics. This led to a lengthy and fruitful period of collaboration with a number of workers, particularly at the National Institute for Research in Dairying, where he provided the statistical basis for the biological work. He also worked with Bond on precise measurements of gas viscosity, and was a founder member of the British Rheologists Club. The demands of war-time teaching developed an unexpected competence in astrophysics and meteorology. After the Second World War, expansion of the University and the shortage of mathematicians led Paul White to transfer to the Department of Mathematics, with special responsibility for the development and teaching of applied mathematics. This marked the end of direct personal and individual research, but he continued to help many people in other disciplines with the mathematical aspects of their work.

White led a very full life in the University; he lived in St. Patrick's Hall, of which he was Senior Resident, sang in the Choral Society and coached an eight on the river—he always undertook the timekeeping of the Head of the River race with enthusiasm and meticulous attention. No account of Paul White's life could be complete without reference to his Christian faith and work. He was a truly devout man, an ardent and active Congregationalist and a staunch supporter of the Student Christian Movement. A lay preacher from his Cambridge days, he was always a welcome preacher in Congregational pulpits over a wide area.

K. W. ALLEN

#### Dr. C. W. Farstad

CHRISTIAN W. FARSTAD, who was awarded the Gold Medal of the Entomological Society of Canada last year, died at the age of sixty, on November 18, after an operation in a Toronto hospital. He had made many contributions to the control of insect pests; his sawfly resistant variety of wheat has been of particular value.

Born in Norway, Farstad went, with his family, to America, where he was educated. He obtained his B.Sc. and M.Sc. from the University of Saskatchewan and his Ph.D. from Iowa State College. During this time he began his career as an entomologist in 1929, when he became an assistant in field investigations of grasshopper and cutworms at the Dominion Entomological Laboratory at Lethbridge; in 1945 he became the laboratory's chief. In 1935 he took charge of the work on the control of wheat stem sawfly. By 1946 the first solid stemmed spring wheat variety resistant to sawfly, named "Rescue", was available to farmers. This came out of an accumulation of knowledge and experience built up by Farstad with his assistants; his expertise was recognized when he was made director of the Plant Protection Service in 1959. Here he led the organization which was able to identify the golden nematode on Vancouver Island and introduce control measures very rapidly in 1965.

Farstad further contributed to entomology with his activities in the Entomological Society of Canada, of which he had been president. He was also a Fellow of the American Society for the Advancement of Science.

# UGA: A Third Nonsense Triplet in the Genetic Code

by

S. BRENNER

L. BARNETT

E. R. KATZ

F. H. C. CRICK

M.R.C. Laboratory of Molecular Biology,  
Hills Road,  
Cambridge

Two base triplets of the genetic code are known not to represent any amino-acid. It now appears that, in *Escherichia coli*, the UGA triplet of the bases uracil, guanine and adenine does not code for an amino-acid and is therefore also a "nonsense triplet".

Most of the sixty-four triplets of the genetic code<sup>1</sup> have been allocated to one or other of the twenty amino-acids. The two known nonsense triplets (UAA, *ochre* and UAG, *amber*) are believed to signal the termination of the polypeptide chain. The only other triplet so far unallocated is UGA, for which binding experiments give uncertain or negative results.

In this article we show that UGA is "unacceptable" in our system (*Escherichia coli* infected with bacteriophage T4) and present suggestive evidence that it is nonsense; that is, that it does not stand for any amino-acid. Theoretical arguments make it likely that there is no transfer RNA (tRNA) to recognize it. The reason for this apparent absence of function is not yet known. Neither is it known whether UGA is nonsense in other organisms.

Evidence that UGA may be nonsense in *E. coli* has also been presented by Garen *et al.*<sup>2</sup> They investigated the reversion of *amber* and *ochre* mutants in the alkaline phosphatase gene of *E. coli*. *Amber* mutants (UAG) reverted, as expected, to seven different amino-acids including tryptophan which is coded by UGG. *Ochre* mutants (UAA) reverted to six of these amino-acids, but not to tryptophan. This negative result makes it unlikely that UGA stands for tryptophan (see also Sarabhai and Brenner<sup>3</sup>) and suggests that it might be a nonsense codon.

*Mutant X655 contains UGA.* Much of our genetic work has been concerned with the left-hand end of the B cistron of the *rII* region of bacteriophage T4. We have made extensive and detailed investigations of this region which are being reported elsewhere<sup>4</sup>. The mutant X655 occurs in the middle of this region. In brief our proof that X655 contains the triplet UGA consists in converting it to an *ochre* (UAA), using mutagens the behaviour of which is already known.

X655 was induced from wild type by 2-aminopurine, and identical mutants are also found after treatment of wild type phage with hydroxylamine. This shows that it differs from an acceptable triplet by a G-C to A-T base pair change in the DNA. It is not suppressed by any *amber* or *ochre* suppressor (Table 1) and is therefore neither UAG nor UAA. The reversion properties of X655 are shown in Table 2. It is strongly induced to revert to *r*<sup>+</sup> by 2-aminopurine, as is expected, but there is no induction to *r*<sup>+</sup> by hydroxylamine. Thus the triplet in the DNA either contains no G-C pairs or, if it does contain one, it is connected to another unacceptable triplet by a G-C to A-T transition.

The triplet is in fact connected to UAA by a transition, because X655 can be converted to an *ochre* and this change is induced by 2-aminopurine (Table 2). The nature of the

transition is more precisely specified by the finding that the conversion to an *ochre* is induced by hydroxylamine and that the *ochre* triplet produced does not require any replication for expression. Using a previous argument<sup>5</sup> this result suggests that the change arises from a G→A change in the messenger RNA. Because X655 is not an *amber*, this proves that it contains the triplet UGA. To confirm that an *amber* at the site of X655 would be suppressed by *amber* suppressors the X655 *ochre* has been converted to an *amber* by mutation and its properties tested (Table 1).

Table 1. SUPPRESSION PROPERTIES OF X655 AND ITS DERIVATIVES

Mutant	Triplet	<i>Amber</i> suppressors				<i>Ochre</i> suppressors		
		<i>su</i> <sup>-</sup>	<i>su</i> <sub>I</sub> <sup>+</sup>	<i>su</i> <sub>II</sub> <sup>+</sup>	<i>su</i> <sub>III</sub> <sup>+</sup>	<i>su</i> <sub>B</sub> <sup>+</sup>	<i>su</i> <sub>C</sub> <sup>+</sup>	<i>su</i> <sub>D</sub> <sup>+</sup>
X655	UGA	0	0	0	0	0	0	0
X655 <i>ochre</i>	UAA	0	0	0	0	+	+	+
X655 <i>amber</i>	UAG	0	+	+	+	+	+	+

Phage stocks were plated on the following strains: *su*<sup>-</sup>, CA244; *su*<sub>I</sub><sup>+</sup>, CA268; *su*<sub>II</sub><sup>+</sup>, CA180; *su*<sub>III</sub><sup>+</sup>, CA265; *su*<sub>B</sub><sup>+</sup>, CA165; *su*<sub>C</sub><sup>+</sup>, CA167; and *su*<sub>D</sub><sup>+</sup>, CA248.

Table 2. REVERSION OF X655

	Reversion index (in units of 10 <sup>-7</sup> )			
	Spontaneous	2-Aminopurine	Hydroxylamine direct	Hydroxylamine after growth
to <i>r</i> <sup>+</sup>	4	312	5	6
to <i>ochre</i>	4	51	1,090	533

X655 was treated with 2-aminopurine and hydroxylamine as previously described<sup>4,5</sup>. Total phage was assayed on *E. coli* B and *r*<sup>+</sup> revertants on CA244 (*su*<sup>-</sup>). *Ochre* revertants were selected on CA248 (*su*<sub>D</sub><sup>+</sup>) and distinguished from *r*<sup>+</sup> revertants by picking and stabbing about 300 plaques into CA248 and CA244.

*Other occurrences of UGA.* In three cases we have been able to produce the triplet UGA by selected phase shifts in our region. When (+ -) phase shifts are made over the first part of the B cistron, the two phase shift mutants frequently do not suppress each other. We have shown<sup>4</sup> that these barriers to mutual suppression are due to the generation of unacceptable triplets in the shifted frame. One of these barriers, *b*<sub>1</sub>, has been identified as an *amber* and two others, *b*<sub>3</sub> and *b*<sub>4</sub>, as *ochres*. Three barriers, *b*<sub>2</sub>, *b*<sub>5</sub>, and *b*<sub>6</sub>, have now been identified as UGA by their base-analogue induced reversion to *ochres*. In each case the identification has been checked by converting the *ochre* to an *amber* at the same site.

Tryptophan is represented by the single codon UGG. It would therefore be expected to mutate by transitions to both UAG (*amber*) and UGA, and thus in such cases *amber* and UGA mutants should occur in close pairs. The *amber* mutant, HB74, which maps close to X655,

is an example of this. Genetic crosses between it, X655, and the *ochre* and *amber* derived from X655, show that HB74 maps identically to the *amber* derived from X655, as expected (Table 3).

Table 3. RECOMBINATION BETWEEN VARIOUS MUTANTS

	X655	X655 <i>ochre</i>	X655 <i>amber</i>	HB74	Triplet
X655	0				UGA
X655 <i>ochre</i>	0	0			UAA
X655 <i>amber</i>	+		0		UAG
HB74	+	0	0	0	UAG

The phages were crossed in *E. coli* B and the complexes irradiated with ultra-violet light to stimulate recombination (see ref. 4). In the Table, 0 means that  $r^+$  recombinants were not significantly above the reversion rate, which was between  $2$  and  $9 \times 10^{-7}$ ; in those experiments where positive results were obtained (+), the frequency was between  $2$  and  $6 \times 10^{-5}$ .

So far we have found the expected pairs consisting of UGA and an *amber* in two other cases. In the A cistron, a mutant X665\* is found with the *amber* mutant N97, and in the B cistron, N65 is paired with the *amber* mutant X237. Both N97 and X237 are likely to have arisen from UGG (tryptophan) which is confirmed by the finding that they respond only poorly to the *amber* suppressor *su*<sub>11</sub> which inserts glutamine<sup>5</sup>. Both X665 and N65 have been converted into *ochre* mutants, showing that they contain the triplet UGA. These *ochres* have also been converted to *ambers* at the same site. Mapping investigations, analogous to those in Table 3, are consistent with these allocations.

**Unacceptability of UGA.** There is very good evidence that the amino-acid sequence coded by the first part of the B cistron is not critical for the function of the gene<sup>4</sup>. It can be replaced by varying lengths of the A cistron using deletions that join the two genes. Moreover, an extensive (- +) frame shift can be made without noticeable effect on the function. Of the fifteen known base-analogue mutants in the region, thirteen are either *ochres* or *ambers*; one, HD263, is temperature sensitive and X655 is UGA. The extreme bias towards *amber* and *ochre* chain-terminating mutants confirms the dispensability of the region<sup>4</sup>. These results make it unlikely that the unacceptability of UGA in X655 and the three barriers results from the insertion of an amino-acid, and strongly suggest that it is nonsense.

In addition, the UGA mutant X665 in the A cistron has been combined with the deletion r1589 and has been found to remove the B activity of this phage. This is the test for nonsense originally used by Benzer and Champe<sup>6</sup>.

In all these cases, however, it could be argued that UGA might code cysteine, especially as the two known triplets for cysteine are UGU and UGC. If the B protein already contained a cysteine essential for its function the effect of UGA elsewhere might be to produce an S-S bridge between the cysteine inserted by UGA and the (hypothetical) essential one, and thus inactivate the protein. Nevertheless we regard this as unlikely for two reasons, one genetic and one chemical.

The genetic evidence concerns the anomalous minutes produced by certain (+ +) combinations in the B cistron<sup>4</sup>. In some regions of the first part of the B cistron combinations of two (+) phase shift mutants are able to grow to some extent on the restrictive host, *E. coli* K12. The plaques produced are minute, however, showing that the wild type phenotype is very far from being completely restored. A detailed analysis of one set of these combinations showed that minutes are obtained only from pairs of (+) mutants which straddle barrier *b*<sub>4</sub>. The presence of the barrier is obligatory because, if it is removed by mutation, the (+ +) doubles are unable to grow at all on *E. coli* K12. The minutes are clearly due to a phase error of one sort or another and the phase error is dependent on the barrier *b*<sub>4</sub> which we now know to be UGA. This result shows that UGA cannot be associated with any

normal amino-acid reading and points strongly to the conclusion that it is nonsense.

The chemical reason for UGA not coding for cysteine comes from the work of Khorana *et al.*<sup>7</sup>. They have shown that poly (UGA)<sub>n</sub> when used as a messenger in a cell-free system derived from *E. coli* induces the production of poly methionine (corresponding to AUG) and also poly aspartic acid (corresponding to GAU). No other amino-acid appears to be incorporated. In particular, no poly cysteine was found. For various reasons this evidence is not completely decisive, but it at least makes it unlikely that UGA is cysteine.

**Function of UGA.** It might be thought that the sequence containing UGA was nonsense because it was the signal for the beginning or ending of a gene (or operon). In other words, that it produced its effect during the synthesis of the messenger RNA on the DNA template of the gene. This explanation is highly unlikely because the effects of UGA depend on it being read in phase. The phenotypic effect of X655 can be removed when the mutant is placed in a (- +) shifted frame<sup>4</sup>, and the barriers *b*<sub>2</sub>, *b*<sub>3</sub> and *b*<sub>4</sub> are of course produced by phase shifts. That is, the base sequence UGA actually occurs at these places in the wild type messenger RNA but in such a way that it is out of phase when the message is read correctly. Because we have no reason to suspect that RNA polymerase synthesizes messenger RNA in groups of three bases at a time these results imply that the phenotypic effects of UGA must occur during protein synthesis.

It thus seems unlikely that UGA codes for any amino-acid, and in particular it does not appear to code for either cysteine (UGU and UGC) or tryptophan (UGG). The wobble theory of codon-anticodon interaction developed by one of us<sup>8</sup> makes the prediction that because of a wobble in the recognition mechanism at the third place of the codon no tRNA molecule can recognize XYA alone without at the same time recognizing either XYG or both XYU and XYC. Such theoretical arguments cannot be considered conclusive, but they certainly suggest that UGA is a triplet for which no tRNA exists. For this reason we think it unlikely that UGA produces the efficient termination of the polypeptide chain, but more direct evidence will be needed to establish this point.

**Conclusion.** We have thus established that in the phage-infected cell UGA is certainly "unacceptable" in the rII cistrons, although it remains to be seen whether this is true for other species. We have produced reasons why it is unlikely to code for any amino-acid. We are confident that there must be weighty reasons if even a single triplet is not used in the genetic code, because otherwise natural selection would have certainly allocated it to an amino-acid. At the moment we are inclined to believe that UGA may be necessary as a "space" to separate genes in a polycistronic message. It is possible to make a plausible theory for *E. coli* along these lines, but we prefer to leave the discussion of this until we have more experimental evidence to support it. This we are at present attempting to obtain.

We thank Drs. A. Garen, H. G. Khorana and A. Sarabhai for interesting discussions and for showing us their papers in advance of publication. One of the authors (E. R. K.) is a holder of a United States Churchill Foundation scholarship.

# Intracellular Potassium and Macromolecular Synthesis in Mammalian Cells

by  
MARTIN LUBIN

Department of Pharmacology, Harvard Medical School, Boston, Massachusetts

The surface properties of cells may affect their ability to synthesize large molecules. These experiments raise the question whether the intracellular potassium concentration affects the synthesis of proteins and nucleic acids.

SURPRISINGLY little is known about the connexions between the surface activities of animal cells and the control of cell growth. This article describes the results of some simple experiments which suggest one possible connexion: that between the regulation of intracellular potassium concentrations and the synthesis of macromolecules.

These experiments were an outgrowth of our previous work on the control of bacterial growth, which showed that for at least two organisms, *Escherichia coli* B and *Bacillus subtilis*, the concentration of intracellular potassium sets the rate of protein synthesis<sup>1,2</sup>. With bacteria, it was possible to change the concentration of intracellular potassium at will by using mutants that did not accumulate potassium normally. For the present experiments on animal cells, analogous mutants were not available, but cell potassium concentrations could be manipulated by adding amphotericin B to the medium—this drug attaches irreversibly to steroids in the cell membrane and produces graded leaks of small molecules<sup>3</sup>. The amphotericin B used was the Squibb product, containing 41 mg sodium deoxycholate for each 50 mg of amphotericin.

With the loss of cell potassium caused by amphotericin there was a parallel depression of the rates of synthesis of protein and DNA. If the amount of potassium in the medium was increased, nearly normal levels of cell potassium could be sustained in these leaky cells and the depression of macromolecular synthesis could be largely prevented. The results are consistent with the hypothesis that in animal cells, as in bacteria, the level of intracellular potassium controls the rate of macromolecular synthesis.

Sarcoma-180 (S-180) cells were cultured in suspension at 37° C in Eagle's spinner medium, supplemented with both essential and non-essential amino-acids and with 10 per cent horse serum<sup>4</sup>. Doubling time was 1 day and cell densities ranged from 3 to 6 × 10<sup>5</sup> cells/ml. In order to measure the kinetics of potassium influx, potassium-42 chloride was added to growing cell suspensions; samples were removed periodically and collected on SS 'Millipore' filters (3 μ pore size) under soft suction equivalent to 2 cm of water. Cells on the filters were rinsed briefly with Eagle's medium and the radioactivity retained on the filter was measured in an end-window counter. The steady state potassium content of normally growing S-180 cells was estimated by equilibrating the cells with potassium-42, centrifuging a concentrated suspension in a haematocrit tube, and determining the potassium-42

content and volume of the packed cells. The results were corrected for extracellular fluid trapped in the pellet, as determined by the content of <sup>14</sup>C-sucrose in the pellet. The potassium concentration of normal S-180 cells was 135 ± 20 mmoles/l. Measurements of intracellular specific activity showed that the amount of potassium-42 contained in cells in the steady state was proportional to the intracellular potassium content.

For measurements of macromolecular synthesis, <sup>14</sup>C-leucine, uridine or thymidine was added to the medium; samples were collected at intervals on 'Millipore' filters under soft suction, and the filters were rinsed briefly with Eagle's spinner medium without horse serum to wash off excess protein. When only a small amount of fluid remained above the filters, 5 ml. of cold 10 per cent trichloroacetic acid was added; after 1 min, the filters were sucked dry, washed briefly with water and the radioactivity retained was counted. This procedure adequately traps all trichloroacetic acid precipitable material on the filters.

**Reduced potassium levels after amphotericin B.** S-180 cells took up potassium-42 with a half-time of 25 min (mean of four experiments). In a typical experiment (Fig. 1), 1, 2 and 3 μg/ml. of amphotericin reduced the steady state concentration of potassium-42 to about 85, 40 and 30 per cent of the control level. No obvious change in cell volume occurred for about 2 h. After many hours and high concentrations of drug (3 to 30 μg/ml.), however, considerable damage was apparent; cells became swollen and permeable to trypan blue. A similar lag between potassium loss and haemolysis has been reported for erythrocytes exposed to amphotericin<sup>5</sup>.

Increase in permeability was also readily detected by measuring the efflux of potassium-42 from prelabelled cells. The response to the drug was prompt; as little as 1 μg/ml. more than doubled the efflux of potassium-42 within 5 min of the addition of drug.

**Protein, RNA, and DNA synthesis.** In most experiments, cells were incubated with amphotericin for 30–60 min to allow a new steady state concentration of potassium to be reached, and the incorporation of <sup>14</sup>C-leucine, uridine, or thymidine was then measured. At low concentrations of amphotericin, the rate of protein synthesis reached a new steady level at each concentration of drug (Fig. 2). After initial equilibration of cells with the drug for 60 min, the rate of synthesis in the presence of 1, 2 and 3 μg/ml. of drug was 80, 38 and 22 per cent of control. Incorporation of <sup>14</sup>C-thymidine into DNA was depressed

to about the same extent as incorporation of  $^{14}\text{C}$ -leucine. Thus the decrease in the intracellular level of potassium (Fig. 1) and the decreases in the rates of synthesis of protein and DNA were nearly proportional. At all concentrations of amphotericin (1–20  $\mu\text{g}/\text{ml}$ .) depression of RNA synthesis was only about half that of protein synthesis.

Fig. 1. Uptake of potassium-42 by S-180 cells after incubation for 60 min with amphotericin B, at either zero (○), 1 (□), 2 (●) or 3 (Δ)  $\mu\text{g}/\text{ml}$ .

**Reversal of inhibition of protein synthesis by media containing high concentrations of potassium.** These results showed that amphotericin produced both a loss of potassium and a reduced rate of protein and DNA synthesis. It was not clear, however, whether most of the depression of synthesis was due specifically to loss of potassium or to loss of other essential small molecules that may have leaked out.

Parallel experiments were therefore carried out in which incorporation of leucine (or thymidine) was measured in the presence of a modified Eagle's spinner medium, in which all of the sodium, except for the modest amount contained in the supplement of horse serum, was replaced by potassium, mole for mole. Fully substituted medium is referred to as 140 mmolar potassium Eagle's medium; normal Eagle's medium contains 5 mmoles of potassium per litre.

In preliminary experiments, it was found that 140 mmolar potassium Eagle's monolayer medium was toxic to S-180 cells. Cells in the corresponding 100 mmolar potassium Eagle's monolayer medium, however, proliferated almost as well on glass surfaces as control cells, and in 100 mmolar potassium Eagle's spinner medium the rate of leucine incorporation was about 85 per cent of the control value (mean of four experiments). Experiments on the reversal of amphotericin effects were therefore largely confined to media containing 100 mmolar potassium or less.

The typical experiment of Fig. 3 shows that amphotericin at 8.5  $\mu\text{g}/\text{ml}$  depressed protein synthesis after 60 min to 10 per cent of the control rate. In the presence of

100 mmolar potassium Eagle's medium, however, the same dose of drug depressed protein synthesis to only 60 per cent of the control rate. The reversal by high levels of potassium is striking, and similar results were repeatedly obtained over a wide range of concentrations of amphotericin. With low concentrations of amphotericin (for example, 2  $\mu\text{g}/\text{ml}$ .) and a medium rich in potassium, the rate of protein synthesis was depressed by less than 10 per cent of control values.

Loss of potassium was also produced by high levels of histones or polylysine<sup>6,7</sup>. Protein synthesis was strongly depressed by 100  $\mu\text{g}/\text{ml}$  of histone, but in the presence of 100 mmolar potassium Eagle's medium, the depression was small (Fig. 4). In other experiments, inhibition of incorporation of  $^{14}\text{C}$ -thymidine by amphotericin or by histone was similarly largely prevented by increasing the level of potassium in the medium. In a typical experiment, incubation of S-180 cells for 1 h with 100  $\mu\text{g}/\text{ml}$  of histone reduced incorporation of  $^{14}\text{C}$ -thymidine to 25 per cent of the control rate; but with cells suspended in 100 mmolar potassium Eagle's medium, histone reduced incorporation to only 80 per cent of the control rate.

Fig. 2. Incorporation of  $^{14}\text{C}$ -leucine into protein by S-180 cells after incubation for 60 min with amphotericin B, at either zero (○), 1 (□), 2 (●) or 3 (Δ)  $\mu\text{g}/\text{ml}$ .

The following related results were also found: (1) the addition of 2 mmolar calcium chloride to the medium did not reverse the depressant effects of amphotericin; (2) deoxycholate, when added in amounts equivalent to that present in the preparation of amphotericin B, had no effect on macromolecular synthesis in intact cells; (3) amphotericin did not inhibit protein synthesis by direct action on polypeptide synthesis, as was shown by measurement of the incorporation of  $^{14}\text{C}$ -leucine in a microsomal system derived from rat liver; (4) measurements were made of the fraction of cells that became permeable to trypan blue after incubation with amphotericin; although cells had lost up to 50 per cent of their potassium after 2–3  $\mu\text{g}/\text{ml}$  of drug, less than 3 per cent of the cells had become permeable to trypan blue; the potassium loss

was not therefore due to total disruption of a sensitive fraction of the cell population, but was shared by the bulk of the cells; (5) amphotericin, in amounts up to 20  $\mu\text{g}/\text{ml.}$ , over a period of several hours, did not increase the rate of loss of prelabelled proteins; after many hours, however, or at higher concentrations of drug, leakage of protein was high (up to 50 per cent/h at 50  $\mu\text{g}/\text{ml.}$ ); (6) some of the experiments reported here were also carried out with *L*-cells in suspension culture; in these cells, amphotericin (5–10  $\mu\text{g}/\text{ml.}$ ) was found to inhibit protein synthesis considerably more than RNA synthesis; when protein synthesis was 15 per cent of the control rate, RNA synthesis was still 50 per cent; as with *S*-180 cells, the depression of macromolecular synthesis in *L*-cells by amphotericin was largely reversed by high concentrations of potassium; in two experiments, however, high levels of potassium did not reverse the depression of protein synthesis produced by histone (100  $\mu\text{g}/\text{ml.}$ ); (7) in preliminary experiments, ouabain at high concentrations (0.3–1 mmolar) was also found to reduce cell potassium and inhibit protein synthesis in *S*-180 cells; (8) doubling or halving the amino-acid content of Eagle's medium had no significant effect on the results, which indicates that the size of the amino-acid pool did not limit the rate of protein synthesis in leaky cells.

Fig. 3. Effect of high and low potassium media on protein synthesis after amphotericin B.  $\Delta$ , Control;  $\circ$ , incorporation in 5 mmolar potassium Eagle's medium, with 8.5  $\mu\text{g}/\text{ml.}$  of amphotericin B;  $\blacktriangle$ , 8.5  $\mu\text{g}/\text{ml.}$  of drug, but 100 mmolar potassium Eagle's medium.

Two inferences can be drawn from the results: (1) the depression of macromolecular synthesis in the presence of amphotericin B can be specifically reversed by increasing the level of intracellular potassium; and (2) only a small decrease in intracellular potassium is needed to produce a proportional decrease in macromolecular synthesis.

It must be stated explicitly, however, that the results do not distinguish between a direct effect of potassium levels on macromolecular synthesis, and indirect effects, such as inhibition of synthesis or utilization of ATP, or of glycolysis (see ref. 3 for the effect of potassium levels on glycolysis in yeast). Moreover, the loss of potassium

from mammalian cells is known to be largely compensated for by a gain in sodium, and these preliminary results could equally well be attributed to a change in the potassium/sodium ratio.

One practical result is of interest: of the sizable number of agents which have been found to depress macromolecular synthesis or growth of mammalian cells in culture, some may have as their common mode of action simply a loss of cell potassium.

Fig. 4. Inhibition of protein synthesis by histone.  $\Delta$ , Control, cells in 5 mmolar potassium Eagle's medium, no drug;  $\bullet$ , cells in 100 mmolar potassium Eagle's medium;  $\circ$ , 5 mmolar potassium Eagle's medium plus 100  $\mu\text{g}/\text{ml.}$  of histone;  $\blacktriangle$ , 100 mmolar potassium Eagle's medium plus 100  $\mu\text{g}/\text{ml.}$  of histone. The histone used was the Sigma 3,000 fraction.

Although it is unclear whether the findings are relevant to cell growth within intact animals, some conjectures may be worth considering and testing experimentally. For example, cells in normal tissue, unlike those in tumour tissue, were recently found to possess low resistance junctions<sup>8</sup>. If potassium and sodium are involved in control of cell growth, such junctions may serve to equalize the cation concentrations throughout a communicating set of cells and thereby regulate the common rate of growth. In addition, normal and tumour cells differ in their growth responses to the solid substrate on which they may lie; normal cells in confluent monolayers exhibit a high degree of contact inhibition<sup>9</sup>. One possible explanation that has not been fully examined is that the nature of the cell surface and its contacts affects the leak or pump rate of monovalent cations, and that inhibition of growth on an unfavourable surface may be partly due to a decreased intracellular potassium/sodium ratio.

This work was supported by grants from the U.S. Public Health Service and the U.S. National Science Foundation. I thank Miss Marie-Pierre Gabathuler and Dr. A. Farnham for most of the *S*-180 and *L*-cell cultures, Mrs. Karen Pulley for technical help, and Dr. H. J.-P. Ryser for his comments.

# Nucleic Acid Synthesis in Seedlings

by

K. K. LONBERG-HOLM

Central Research Department,  
Du Pont Experimental Station,  
Wilmington, Delaware

As little as one part in  $10^7$  by weight of contaminating bacteria can alter the labelling of seedling nucleic acids with phosphorus-32. The bacterial nucleic acids are labelled in preference to those of the plant cells. With seedlings free of bacteria the labelling occurs at a slower rate. Systems involving the labelling of nucleic acids should be tested for bacterial contamination.

CONTAMINATING bacteria can contribute to the labelling patterns of the macromolecules of rapidly growing tissues. This has already been shown to be possible in the case of fertilized sea urchin eggs<sup>1</sup> and it is here illustrated with lettuce and radish seedlings. These seedlings have a normal bacterial flora which produces a labelling pattern similar to that previously reported to be characteristic of tissues from other seedlings<sup>2-5</sup>. The similarity in the labelling patterns does not necessarily mean that the earlier results also arise in whole or part from artefacts, but it does show the need to test as carefully as possible for the contributions of bacteria in future investigations of this type.

Bacterial contamination in seedlings is hard to eliminate. "Surface-sterilization" does not always work; for example, Green and Gordon found low levels of bacterial contamination and substantial levels of bacterial DNA synthesis in seedlings germinated aseptically from "sterilized" tobacco seeds<sup>6</sup>. The use of antibiotics in addition to surface-sterilization is not always effective or desirable. The bacteria also cannot be washed from the seedlings—a method which was effective with sea urchin eggs<sup>1</sup>.

The methods usually used to treat and to germinate seeds for labelling experiments are as follows: Two grams of lettuce seeds (Asgrow, 'Grand Rapids') or radish seeds (Burpee, 'Rapid Red') were rinsed in ethanol and then washed 20 min in 100 c.c. of neutral 1 per cent sodium hypochlorite and rinsed with sterile water. They were germinated for 3 days in sterilized covered glass trays lined with filter paper and wetted with 18 ml. of either sterile water or the antibiotic solutions described below. The last 2.5 days of germination were in darkness.

For labelling with phosphorus-32, trays of dark-grown seedlings were transferred under dim green light to a light-tight box and moved to the isotope laboratory where a neutral solution of carrier-free <sup>32</sup>P-sodium or ammonium phosphate (10 or more mc.) was injected by way of an inlet tube. The box was equipped with a tray-sized paddle on a sliding shaft so that the seedlings could be pressed down and wetted occasionally during the exposure. At the end of the exposure the box was opened to the light, and the plants were washed *in situ* with a stream of ice cold 2 mmolar carrier phosphate and with an aspirator for drainage.

Nucleic acids were extracted by homogenizing the seedlings at "high speed" for 75 sec in an 'Osterizer' in ten volumes of an ice-cold slurry of 1 per cent sodium dodecyl sulphate containing 0.02 molar *tris* buffer pH 8 (measured at 22° C), 0.1 molar sodium chloride and 5 mmolar mercaptoethanol. Eight additional volumes of redistilled phenol (containing 10 per cent aqueous 1 mmolar ethylenediamine tetraacetic acid (EDTA)) were added, the mixture was again blended for 15 sec, and mechanically shaken for 15 min in the cold room. The aqueous layer was separated by centrifugation and saved and the remainder was re-extracted with the detergent slurry. The aqueous layers were pooled, re-extracted with phenol, and mixed with 0.1 volumes of 20 per cent

potassium acetate pH 5.3 and 2.5 volumes of cold ethanol to precipitate the nucleic acids. After one night in the refrigerator, the precipitate was centrifuged and washed with 70 per cent ethanol. It was then redissolved in the detergent slurry and extracted once again with phenol, re-precipitated, washed, and dissolved in a few millilitres of 0.05 per cent sodium dodecyl sulphate in dilute *tris* buffer and stored frozen. The discarded solid residues from the initial phenol extractions of seedlings free from bacteria contained relatively little additional labelled RNA; 5 per cent more, at most, could be extracted with detergent and phenol at 60° C.

For bacterial assay, samples of seedlings from the isotope exposure step were homogenized in isotonic saline. Colony counts were made on diluted aliquots of the homogenate which were spread and incubated for several days at room temperature on nutrient agar.

Radish seedlings from seeds treated with hypochlorite were often "free from bacteria" (which is defined for these experiments as less than  $10^3$  bacteria/g) while untreated seeds yielded seedlings with about  $10^8$  bacteria/g. Even with hypochlorite treatment, lettuce seedlings grown in water contained more than  $10^8$  viable bacteria/g wet weight. Among the bacteria found in lettuce and radish seedlings were *Corynebacterium* sp., various pseudomonads, *Flavobacterium* sp. and *Bacillus macerans* (McCoy, E., personal communication).

Sterile lettuce seedlings could sometimes be germinated from seeds treated with hypochlorite in a standard antibiotic mixture composed of 100 U/ml. penicillin G and 'Mycostatin' and 100 µg/ml. streptomycin sulphate and 'Aureomycin' or in the standard mixture without 'Aureomycin'. Even under these conditions, lettuce seedlings were often contaminated with more than  $10^4$  resistant bacteria/g. Lettuce free from bacteria could, however, be grown consistently from seeds treated with hypochlorite that were leached overnight in several-hundred volumes of standard antibiotic mixture while being agitated by a stream of sterile air bubbles. These seeds yielded plants free from bacteria, even when they were germinated in water.

Thirty-three pulse-labelling experiments have been made with lettuce seedlings and nine with radish. Nineteen of the lettuce experiments involved treatment with antibiotics; however, bacterial contamination occurred in six of these.

Fig. 1a shows the gradient centrifugation pattern of an extract from lettuce seedlings contaminated with bacteria. There are large counts for the components insoluble in trichloroacetic acid near the top of the tube (to the left) and in two RNA components (I and II) sedimenting with and between the bulk light and heavy ribosomal RNA. In this separation <sup>32</sup>P-DNA underlies the left side of component I. <sup>32</sup>P-DNA has been identified in other gradients by its resistance to pancreatic ribonuclease and to mild alkaline hydrolysis as well as by chromatography. The sedimentation properties of components I and II resemble those reported for the RNA

labelled in 3 day old cotton seedlings<sup>5</sup> and components seen in the labelled RNA of soybean hypocotyls<sup>4</sup>. Component II resembles the heavy ribosomal RNA (bacterial) found to be labelled in contaminated sea urchin eggs<sup>1</sup> and in general heavy bacterial ribosomal RNA. Component I does not appear to sediment slower than the bulk plant light ribosomal RNA, and this may argue against the theory that it is of bacterial origin.

A peak of labelled RNA sedimenting in the position of component II was only observed in experiments made with contaminated seedlings. Fig. 1b shows that tissue grown in the presence of antibiotics, but containing  $7 \times 10^4$  viable bacteria/g, may still contain this peak.

Fig. 1c shows the sedimentation pattern of nucleic acids from lettuce free from bacteria and treated with antibiotic. Whenever nucleic acids were labelled in seedlings free from bacteria they showed, in addition to slowly sedimenting material, three rather flat sedimentation peaks: (1) a little faster than the bulk light ribosomal RNA; (2) with the heavy ribosomal RNA; (3) about a quarter farther down the tube than the bulk heavy RNA. The slowly sedimenting material is composed partly of non-nucleic acid impurities.

Fig. 1d shows a separation of the RNA from 1c which has been further purified by precipitation at 0° C with 2 molar lithium chloride to remove most of the DNA, transfer-RNA and slower sedimenting impurities. Recovery of material greater than 16S is essentially complete. Table 1 shows the nucleotide composition of components 1, 2 and 3 from the material separated in Fig. 1d. The hydrolysates of these fractions contained no large amount of any unexpected component; a separate experiment with a 'Dowex-1' column showed that the elution of nucleotide radioactivity precisely matched the ultraviolet absorption of the carrier nucleotides. (Nucleotides and nucleotide 2'-3' isomers were separated on a 20 cm column of 400-mesh 'Dowex-1  $\times$  8 Cl-' (Lot 5893-35) with a 600 ml. linear 0.02 normal hydrochloric acid gradient. The 2'-3' isomers of cytidine monophosphate and uridine monophosphate were not resolved. Most samples of 'Dowex-1' were not satisfactory for this separation.)

The results in Table 1 indicate that a high AMP content RNA may be present under components 1, 2 and, to a

Table 1

Per cent	C	A	U	G
Fraction 1	17.1	38.3	24.6	22.0
Fraction 2	17.3	38.7	24.6	24.3
Fraction 3	18.0	30.9	23.9	27.3
(Ribosomal RNA)	24.0	24.5	20.8	30.7

The base composition of the pulse labelled RNAs from lettuce seedlings free from bacteria as the percentage of recovered phosphorus-32 in each ribonucleotide. The sucrose gradient fractions of the RNA purified in lithium chloride shown in Fig. 1d were hydrolysed 18 h in 0.5 normal potassium hydroxide and desalted by the procedure of Strauss and Sinsheimer<sup>14</sup>. Nucleotides were separated electrophoretically by the method of Smith<sup>15</sup> and counted. It was calculated that the ribonucleotides together accounted for 99-101 per cent of the total hydrolysate phosphorus-32. The lettuce ribosomal RNA values were determined by chromatography on 'Dowex-1'; 3-day labelled ribosomal RNA was purified for this on a methylated albumin on kieselguhr column.

lesser extent, 3 in the form of a broadly dispersed peak on which is superimposed normal plant ribosomal RNA and another RNA (component 3) which could be a nuclear ribosomal RNA precursor as has been found in animal tissues<sup>7</sup>. The high AMP-RNA compositions resemble those reported for <sup>32</sup>P-RNA from soybean seedling hypocotyls<sup>4</sup> and roots<sup>8</sup> and from pea seedling roots<sup>9</sup>. RNA such as this has been called "DNA-like" by other authors<sup>4</sup>, despite its low UMP content. Another interpretation of the apparent high AMP content of these RNAs is that there could be non-uniform labelling of precursor 5'-nucleotides within the seedlings and also a non-uniform nearest neighbour frequency in the newly synthesized RNA. These together could give a non-uniform labelling of 3'-nucleotides released from the RNA by alkaline hydrolysis such that 3' AMP would have the highest specific activity<sup>10</sup>.

Figs. 1e and 1f show the sedimentation of pulse-labelled nucleic acids from contaminated and bacteria-free radish seedlings. Because the seeds were sterilized with only alcohol and hypochlorite it is clear that it is the absence of bacteria rather than the presence of antibiotics which causes an important decrease in incorporation and the disappearance of component II. Elimination of bacteria in lettuce or radish caused not only a loss of component II but also at least a seven-fold decrease in the labelling of RNA in the region of component I. This suggests that most of component I from contaminated seedlings is an artefact of bacterial origin and that only a part is genuine RNA (component 1) from the plant cells.

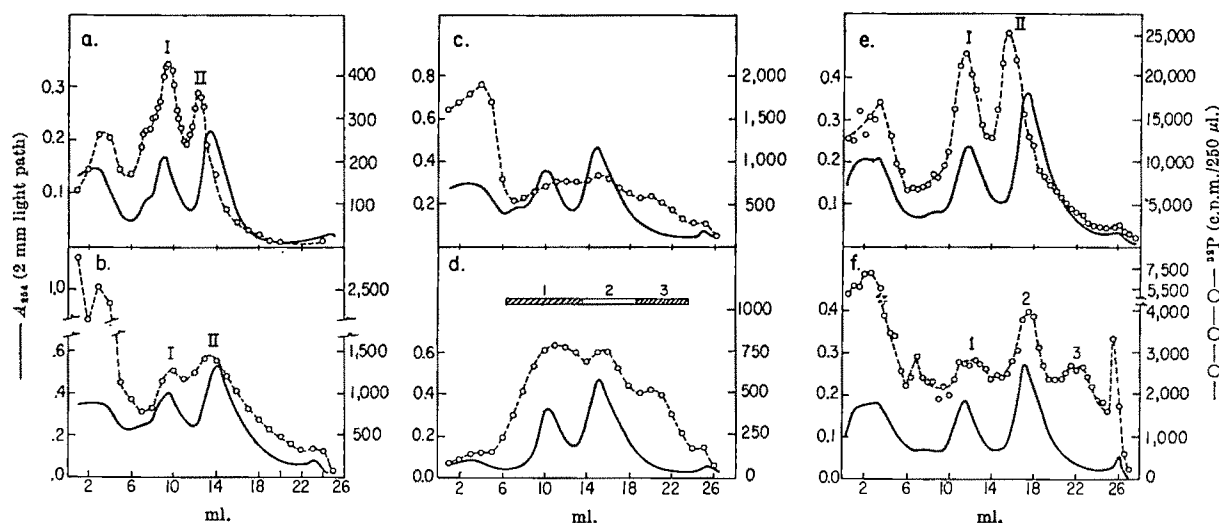

Fig. 1. Sucrose gradient centrifugation of <sup>32</sup>P-nucleic acids from seedlings. The top of each tube is to the left. (a) Contaminated lettuce grown from hypochlorite treated seeds and containing  $10^4$ - $10^5$  bacteria/g (on the basis of analysis of similarly grown samples). After a 20 min labelling 0.06 per cent of the fed phosphorus-32 was recovered in the trichloroacetic acid insoluble components of the extract. (b) Slightly contaminated from hypochlorite treated seeds germinated in "complete antibiotic mixture" and containing  $7 \times 10^4$  bacteria/g. 60 min labelling, 0.011 per cent recovery. (c) Lettuce free from bacteria from antibiotic leached seeds also germinated in the "complete antibiotic mixture". 60 min labelling, 0.008 per cent recovery. (d) Lithium chloride insoluble RNA from c representing 0.005 per cent of the fed phosphorus-32. (Fractions 1, 2 and 3 were pooled from identical gradients for base analysis.) (e) Contaminated radish from untreated seed and containing  $4 \times 10^4$  bacteria/g. 60 min labelling, 0.2 per cent recovery. (f) Radish free from bacteria from seeds treated with alcohol-hypochlorite. 60 min labelling, 0.07 per cent recovery. Separations were made at 2° C in the Spinco S15-25 rotor in a 4-20 per cent gradient of sucrose containing 0.05 molar pH 7.0 Tris buffer and, except in a, 0.05 molar sodium chloride. Gradients b, c and d also contained 0.5 mg/ml. polyvinylsulphate. Fractions were precipitated with carrier serum albumin and trichloroacetic acid for scintillation counting.

Components 1, 2 and 3 from radish were also found in samples purified by precipitation with lithium chloride; these were shown, as with lettuce, to have a high content of AMP.

The standard antibiotic mixture did, in fact, stunt seedling growth. Control experiments with sterile radish indicated that this resulted in a proportionate decrease in the incorporation of isotope. The antibiotics, however, did not cause any important changes in the sedimentation pattern or composition of the labelled RNA.

Other types of experiments with contaminated lettuce seedlings showed that some pulse-labelled RNA could be recovered in a ribosome-like particle which sediments more slowly than the bulk ribosomes and resembles the "nascent" cotton seedling ribosomes of Waters and Dure<sup>6</sup>. This RNA sediments as do components I and II of Fig. 1, but there is relatively more of component II. No component II is found, however, in the labelled RNA from ribosomes of uncontaminated seedlings and in the lettuce system it seems likely that the "nascent" particle is therefore an artefact derived from bacterial ribosomes.

Labelled seedling nucleic acids were also analysed by column chromatography on methylated albumin bound to kieselguhr by the method of Mandell and Hershey<sup>11</sup>. The results of a few of these analyses are shown in Fig. 2. The bulk light and heavy ribosomal RNA from plants could not be clearly separated with the steep elution gradients which I used; light and heavy ribosomal RNA from *Escherichia coli*, however, could.

Elution patterns of labelled extracts of contaminated lettuce seedlings varied somewhat from experiment to experiment (perhaps as a function of the type and extent of bacterial contamination), but a substantial amount of radioactivity always appeared with the first eluting shoulder of light ribosomal RNA. Component I in Fig. 2a is a clear example; components I and II are not always this clearly defined and radioactivity often fills in the valley between them. Even in experiments where these could not be sharply defined by chromatography, gradient centrifugation of the same samples showed the characteristic two peaks associated with bacterial ribosomal

RNA. When the separated components from gradient centrifugation were loaded on and eluted from methylated albumin columns together with carrier lettuce ribosomal RNA, the slower sedimenting one (I) ran largely ahead of the ultra-violet absorbing peak while the faster (II) eluted later. In this sense, components I and II seen in the centrifuge are the same as chromatographic components I and II. Figs. 2c and 2d show that lettuce (antibiotic treated) and radish (no antibiotics) seedlings free from bacteria have very little radioactivity eluting in the region of component I. There is also a relative decrease in the labelling of DNA.

The most salient feature of the chromatography experiments is that seedlings which are contaminated with bacteria always produce a main <sup>32</sup>P-DNA component which elutes in advance of the bulk DNA. This is never apparent when there is no contamination, and a very small amount of bacteria will produce it as is shown in Fig. 2b where the seedlings contained only  $7 \times 10^4$  bacteria/g. The association of this peak with bacterial contamination has also been confirmed by K. Šebesta with cucumber seedlings (personal communication).

Some <sup>32</sup>P-RNA also elutes in the region of the <sup>32</sup>P-DNA peak from contaminated lettuce seedlings. Caesium chloride buoyant density centrifugation has been used to separate both labelled RNA and bulk DNA from this labelled (bacterial) DNA, and so this peak does not contain RNA and DNA in the form of a "chemical association" such as reported in peanut cotyledons<sup>3</sup>. Non-uniform labelling of any chloroplast or other satellite DNA would be hard to detect by the methods used here if it caused (as is reported for tobacco<sup>9</sup>) only a several-fold increase in specific activity relative to the bulk nuclear DNA. This is because the satellite DNA is likely to be present to the extent of only 1 or 2 per cent of the total.

The contributions of bacteria are not linearly proportional to the extent of contamination—there is not a thousand-fold increase in labelled bacterial DNA or RNA when the population is increased from  $10^5$  to  $10^8$ /g plant tissue. A similar non-linearity of bacterial protein synthesis in contaminated chloroplast preparations has been

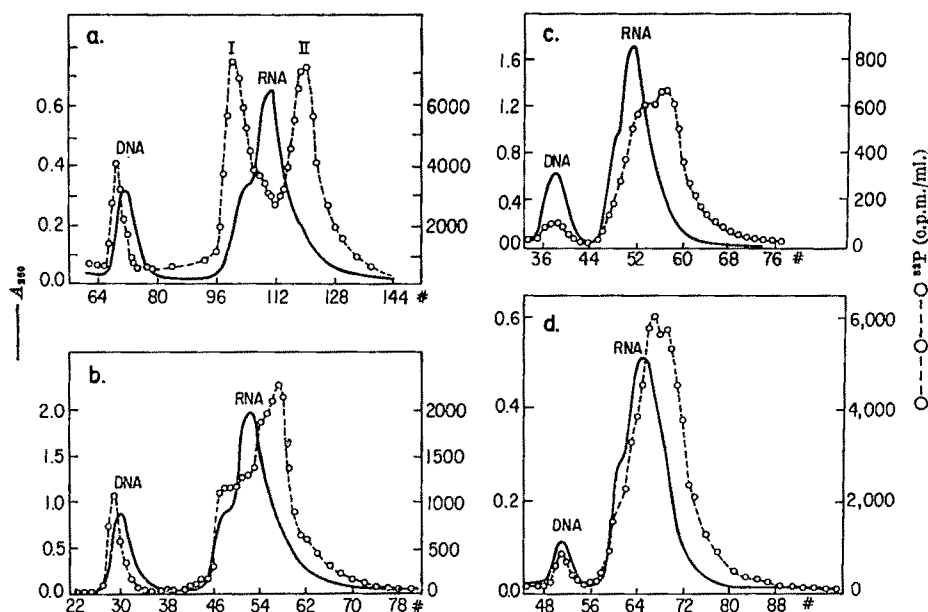

Fig. 2. The chromatographic separation of nucleic acid extracts from seedlings labelled with phosphorus-32. (a) Contaminated lettuce grown from hypochlorite treated seeds and containing  $10^5$ – $10^8$  bacteria/g. 0.2 per cent of the fed phosphorus-32 was recovered in a form insoluble in trichloroacetic acid in the crude nucleic acid extract after a labelling period of 20 min. (b) Slightly contaminated lettuce—the extract used in Fig. 1b. (c) Lettuce free from bacteria from seed treated with hypochlorite germinated in "complete antibiotic mixture" but without 'Aureomycin'. 40 min labelling led to a 0.002 per cent recovery of phosphorus-32 in the extract. (d) Radish free from bacteria from seeds treated with alcohol-hypochlorite. 65 min labelling gave 0.04 per cent recovery. Nucleic acids were loaded on to methylated albumin-kieselguhr and eluted with a linear 0.4–1.5 molar sodium chloride gradient (ref. 11); only the DNA and ribosomal RNA portions of the elution are shown.

reported<sup>12</sup>. This means that it is difficult to test whether or not a given component is bacterial on the basis of whether or not its labelling is decreased by a several-fold decrease in bacterial content, a practice which has been used to discredit the possibility of bacterial artefacts by other workers<sup>13</sup>.

I thank Mrs. Dorothy Lloyd for assistance and Dr. P. G. Heytler for his support and interest. I also thank Prof. E. McCoy and her students at the University of Wisconsin for identifying seedling bacteria and Dr. N. G. Anderson for a special sample of ion-exchange resin.

*Note added in proof.* D. A. Barber has recently also reported that bacterial contamination can profoundly alter phosphorus-32 incorporation into plants (*Nature*, 212, 638; 1966). His results show that bacteria compete with plants for limiting amounts of available phosphate. It seems likely then that bacterial contamination doubly obscures the nucleic acid labelling pattern in seedlings. Not only do rapidly labelled bacterial nucleic acids mask the more slowly labelled plant nucleic acids but also the relative rate of labelling of the latter is further decreased because the bacteria compete for the exogenous phosphorus-32.

## Dual Localization of $\beta$ -Glucuronidase in Endoplasmic Reticulum and in Lysosomes

by

WILLIAM H. FISHMAN

Acid hydrolases are not exclusively lysosomal enzymes as indicated by the specific case of  $\beta$ -glucuronidase. This enzyme is a membrane protein found in the endoplasmic reticulum and in the lysosomes of the cell.

LYSOSOMES are organelles in a particular sedimentable fraction of tissue homogenates. They are characterized by a structure linked latency of their constituent acid hydrolases. A strong bias in favour of an exclusively lysosomal localization of acid hydrolases has developed because the lead salt technique for acid phosphatase demonstrates lysosomes only<sup>1</sup>. Non-lysosomal sites for these enzymes have scarcely been considered. Yet deDuve showed in 1955 (ref. 2) that only about 20 per cent of the total activity of another acid hydrolase,  $\beta$ -glucuronidase, could be found in the lysosomal fraction of centrifuged rat liver, while 40 per cent is present in microsomes.

The present article considers with regard to enzyme staining reactions the validity of non-lysosomal location of  $\beta$ -glucuronidase, contends that dual localizations (lysosomal and non-lysosomal) are to be expected for other acid hydrolases, and suggests a non-lytic function for these enzymes.

In the course of the metal chelate technique<sup>3-5</sup>, fresh tissue specimens (2 × 2 × 5 mm) were fixed in formol chloral hydrate solution for 18 h, washed in running tap water for 2 h, transferred to Holt's 0.88 molar gum sucrose solution for 2 days and then cut on the freezing microtome or cryostat at 7–10 $\mu$ . The sections were carefully placed so as to float freely on the surface of the substrate solution (1 section per ml. in a 16 ml. 'Pyrex' beaker). The Fishman-Baker substrate solutions<sup>6</sup> contained 15.25 mg of 8-hydroxyquinoline  $\beta$ -D-glucosiduronic acid in 0.1 per cent polyvinylpyrrolidone solution<sup>3</sup> at

pH 3.8. After 3 h at 4° C the beakers were covered with 'Parafilm' and incubated in a water bath at 37° C for 30 min. The surface deposit was then removed with filter paper, and the section transferred to distilled water and agitated gently.

The washed tissue was immersed in oxalate buffer for 15 min and briefly returned to distilled water. To convert the ferric iron to Prussian blue, the tissue was treated with an equal mixture of molar hydrochloric acid and 2 per cent potassium ferrocyanide for 15 min, rinsed in distilled water, transferred to a 1 per cent solution of warmed Knox gelatine, placed on a glass slide and allowed to dry in air. The sections were secured to the slides by treatment with 10 per cent formol-calcium for 10 min. Carmalum or neutral red were used as counterstains. The sections were dehydrated routinely and were mounted in 'Technicon'. Those tissues in which the ferric chelate was not converted to Prussian blue were mounted directly (Fig. 1a, rat liver) without dehydration.

In the electron microscope experiments, 40 $\mu$  sections of fresh mouse liver were cut on the cryostat and were fixed in 2.5 per cent glutaraldehyde buffered at pH 7.2 with 0.1 M cacodylate buffer for 30 min<sup>6</sup>. The tissues were removed from the fixative with glass rods, washed five times in 0.1 molar cacodylate buffer pH 7.2 for 10 min and incubated in the Fishman-Baker medium as described, first for 1.5 h at 4° C and then at 37° C for 45 min. After conversion of the ferric chelate to Prussian blue, the sections were cut into 1 mm<sup>2</sup> pieces, dehydrated through graded alcohols and embedded in a mixture of

methyl and butyl methacrylates. Thin sections were cut on a Porter-Blum ultramicrotome, and examined under the electron microscope (Fig. 1b). Boiled tissue sections were used as controls.

Negative reactions were found in sections of fixed rat liver, kidney and muscle previously heated in water at 100° C for 1 min or at 56° C in acetone for 1 h. The mixed substrate controls<sup>3</sup> using the glucosiduronic acids of phenolphthalein, menthol and bacalein showed no reaction at concentrations of 0.001 molar, 0.003 molar and 0.00018 molar, respectively. Saccharolactone inhibited about 50 per cent of the reaction at 0.001 molar concentration and almost all of it at 0.003 molar. The post-incubation azo-dye coupling technique, using naphthol *AS-BI*- $\beta$ -D-glucosiduronic acid<sup>7</sup>, was used at pH 4.5 using the method of Fishman and Goldman<sup>8</sup>.

Ferric chelate deposits were visible throughout the cytoplasm of the parenchymal liver cells (Fig. 1a) es-

pecially bordering the bile canaliculi, and in granules of Kupffer cells in a manner indistinguishable from the naphthol *AS-BI* azo dye pigments<sup>8</sup>. Under the electron microscope (Fig. 1b), the endoplasmic reticulum appeared as a main site of deposition of enzyme products. Lysosomes exhibited accumulations of dense material on their limiting membranes. The boiled tissue sections did not have enough contrast to be photographed.

In Fig. 2a the Prussian blue reaction product is located on the boundaries of the large lipid containing vacuoles and in the intervacuolar cytoplasmic spaces of the preputial gland, as is the 8-hydroxyquinoline-azo-dye pigment (Fig. 2b) product obtained in the absence of ferric ions and in the presence of fast dark blue *R*, and the pigment product of the post-coupling technique with naphthol *AS-BI*- $\beta$ -D-glucosiduronic acid as a substrate (Fig. 2c). These intervacuolar spaces are filled with elements of endoplasmic reticulum and Golgi apparatus<sup>9</sup>.

( $\times 600$ .) *b*, Ferric-8-hydroxyquinoline deposits converted to Prussian blue. Arrows indicate deposits on endoplasmic reticulum. *m*, Mitochondria. ( $\times 20,000$ .)

Fig. 2. Rat preputial gland  $\beta$ -glucuronidase visualized, *a*, by 8-hydroxyquinoline-iron chelate Prussian blue technique, *b*, by 8-hydroxyquinoline glucosiduronic acid-fast dark blue *R* simultaneous coupling reaction, and *c*, by naphthol *AS-BI*- $\beta$ -D-glucosiduronic acid-fast dark blue *R*, post coupling technique. Arrows point to membrane locations. ( $\times 1,200$ .)

Rat cartilage gives almost identical results with the metal chelate and with the azo dye methods (Fig. 3a and b) in that the limiting surfaces of the lipid droplets<sup>10</sup>, but not the lipid interior, carry the larger part of the  $\beta$ -glucuronidase activity of the cells<sup>11</sup>.

In the present investigation, two methods based on widely different principles have shown both lysosomal and non-lysosomal sites of  $\beta$ -glucuronidase activity. The non-lysosomal sites visible in the light microscope are interpreted as the endoplasmic reticulum sites of the electron microscope, an observation which agrees with the biochemical fractionation investigations of deDuve *et al.*<sup>2</sup> and especially of Van Lancker, who emphasized the dual lysosomal and microsomal localization of  $\beta$ -glucuronidase and acid phosphatase in regenerating rat liver<sup>12-15</sup>. Moreover, R. E. Smith has also demonstrated (personal communication) the presence of  $\beta$ -glucuronidase in endoplasmic reticulum and lysosomes in an electron microscope investigation of rat pituitary.

The most widely accepted cytochemical localization of acid phosphatase is exclusively in the lysosomes<sup>1</sup>. The absence of non-lysosomal sites may, however, be a consequence of enzyme inhibition both by formaldehyde or glutaraldehyde fixation and by lead ions in the incubation digests of the lead salt technique. Burstone<sup>16</sup> showed both a "peribiliary pattern of distribution and generalized cytoplasmic reaction" in rat liver with naphthol AS-BI phosphate and red violet LB.

In the case of non-specific esterase<sup>17</sup>, an exclusive peribiliary reaction in rat liver and a droplet reaction in rat kidney contrasts with the predominantly microsomal location found on differential centrifugation<sup>18</sup>. Shnitka and Seligman<sup>17</sup> and DeLellis and Fishman<sup>19</sup> were, however, able to demonstrate clearly both droplet and cytoplasmic activity in tissues that were not inhibited by prolonged formalin fixation or by potassium ferro-ferricyanide in the digest. Finally, esterase activity is present in the endoplasmic reticulum according to the *p*-rosaniline<sup>20</sup> and thiolacetic<sup>21</sup> staining methods.

On the basis of the considerations stated for  $\beta$ -glucuronidase, acid phosphatase and esterase, their lysosomal and non-lysosomal cytoplasmic locations are valid and can be expected to vary in a relative way to one another and also in response to factors such as the nature of the tissue, the species and the physiological and pathological status.

The intense staining of sites reflecting dual enzymorphological localization of acid hydrolases, although it accords with the high enzyme activity of tissue homogenate fractions, does not necessarily indicate the extent of *in vivo* activity, which is now regarded as slight. For example, in tissues maintained in organ culture, much, if not all, the  $\beta$ -glucuronidase activity, as tested in cryostat sections, is present as latent activity (Chayen, personal communication). Moreover, the evidence indicates an almost complete lack of metabolic hydrolysis of steroid glucuronides and sulphates<sup>22-25</sup>, and of adrenaline glucuronide (Drell and Clark, personal communication) which failed to elicit a pressor response in the pithed cocaineized cat.

On the other hand, body fluids such as salivary, gastric and intestinal juices, bile, vaginal and spinal fluids, and especially urine, contain non-latent  $\beta$ -glucuronidase and its substrates in aqueous solution, and these circumstances favour hydrolytic cleavage. Furthermore,  $\beta$ -glucuronidase in bile<sup>27</sup> and in intestinal secretions functions in the enterohepatic circulation of drugs and hormones<sup>26</sup> and, under pathological circumstances which produce a drop in pH, a localized area of intense hydrolysis of glucosiduronic acids may well occur in both body fluids and tissue.

The prominence of non-lysosomal sites of  $\beta$ -glucuronidase associated with endoplasmic reticulum suggests a structural role for the enzyme. The concept that enzyme proteins are ordered in a sequence and in numbers adequate to account for membrane structure is now the accepted

Fig. 3. Rat cartilage  $\beta$ -glucuronidase visualized by, a, 8-hydroxyquinoline-iron chelate Prussian blue technique and, b, by naphthol AS-BI- $\beta$ -D-glucosiduronic acid-hexazonium pararosanilin-post coupling technique. ( $\times 1,200$ .) Arrows point to membrane locations.

explanation of electron transport enzyme mechanisms in the mitochondrion<sup>28</sup>. By analogy, enzyme proteins such as  $\beta$ -glucuronidase, acid phosphatase, cathepsin, ribonuclease, deoxyribonuclease, glucosidase and sulphatase may be similarly ordered, perhaps in association with their respective macromolecular substrates and phospholipid to contribute to the structure of endoplasmic reticulum. It would follow that the fragments of endoplasmic reticulum in the cell cytoplasm could be collected in lysosomes by a process of "budding off" and this would account for the bewildering array of acid hydrolases in these organelles. This hypothesis does not require teleological explanations of their pathological intent. In addition, demands for endoplasmic reticulum formation such as occur in differentiating tissues, in regenerating liver, in neoplastic cell proliferation, in phagocytosis, in cells damaged by toxic agents and in the responses of target tissues to hormone would result in a heightened rate of production of structural membrane (catalytically inactive) proteins. Diluted homogenates of such tissues remove latency, and these solutions would now show striking increases in individual acid hydrolases assayed

under their respective optimal conditions for hydrolysis. These values could now be interpreted equally well as a reflexion of new endoplasmic reticulum or as the release of increased amounts of degenerated endoplasmic fragments with their acid hydrolase activity from lysosomes.

In conclusion,  $\beta$ -glucuronidase has been demonstrated in lysosomal and in non-lysosomal sites, the latter being predominantly endoplasmic reticulum. From a consideration of physiological data, we think that  $\beta$ -glucuronidase is essentially inactive in the cytoplasm of cells. In the absence of a credible generalized hydrolytic function for the enzyme *in vivo*, except for body fluids, and in view of the enzymorphological evidence presented, we suggest that  $\beta$ -glucuronidase may serve as a structural protein of the endoplasmic reticulum. The inferences which have been drawn about a similar role for other acid hydrolases may not only succeed in raising a legitimate doubt about the exclusively lytic role assigned to acid hydrolases in the cell but also present a working hypothesis which can be tested experimentally.

This investigation was supported by grants from the U.S. Public Health Service, the National Cancer Institute, and the American Cancer Society, New York. One of us (W. H. F.) is the recipient of a U.S. Public Health Service Career Research Award.

## “Non-parallel Transport” of Enzyme Protein by the Pancreas

by  
S. S. ROTHMAN

Department of Physiology, Harvard Medical School, and Harvard School of Dental Medicine, Boston, Massachusetts

Pancreozymin differentially enhances the secretion of trypsinogen and chymotrypsinogen by an *in vitro* pancreas. This may suggest selective secretion of these enzymes.

THE transport of large molecules from within cells to the outside, as in the secretion of enzymes by the pancreas, is thought to be largely independent of the properties of the molecule which is secreted. The view that zymogen granules release their contents into the lumen of the pancreatic duct much as if a mixture of gases was pouring out of a number of punctured balloons in a random fashion is now familiar, and was embodied in Babkin's theory that the proportions of different enzymes in pancreatic secretion are determined solely by the relative rates at which they are synthesized<sup>1</sup>. This theory implies that the mechanisms within cells which are responsible for the transport of protein from ribosomes to sites adjacent to the apical plasma membrane of the acinar cell are not selective for specific molecules, and, furthermore, that transport through the plasma membrane out of the cell is a random process which is also unselective. Much, but not all, of the available evidence supports Babkin's theory, but this report describes a process of enzyme secretion in the rabbit pancreas which is apparently selective.

New Zealand white rabbits (*Oryctolagus cuniculus*) of both sexes were fasted for 18–22 h before the experiments. Secretions were collected directly from the pancreatic duct either *in situ* or *in vitro*. Details of the biological preparations and techniques used have been given elsewhere<sup>2,3</sup>. *In situ* investigations were performed with the blood supply to the pancreas left intact, whereas the *in vitro* pancreas was bathed by a Krebs–Henseleit saline buffered with bicarbonate and gassed with 95 per cent

oxygen and 5 per cent carbon dioxide and maintained at 30° C. Collections of the secreted fluid were made at hourly intervals in tared tubes and flow was measured in mg/h. Esterase activities of trypsin and chymotrypsin were determined from the initial velocities of reaction of their hydrolysis of *p*-toluene sulphonyl-L-arginine methyl ester-HCl (TAME) and N-acetyl-L-tyrosine ethyl ester-H<sub>2</sub>O (ATEE) respectively<sup>4,5</sup>. Details of the analytical procedures have been given elsewhere<sup>7</sup>. The hourly enzyme activity output is expressed as units of activity secreted/h, where an activity unit/h is the number of  $\mu$ moles of substrate split/min/g of juice  $\times$  g of juice secreted/h.

Trypsinogen and chymotrypsinogen have similar tertiary structures, are of comparable molecular weight (approximately 22,000–24,000), and are even similar in their amino-acid sequences<sup>8</sup>. On the basis of their similar physical properties and apparent consanguinity we might expect them to be handled similarly by a transport system. Thus they are excellent test molecules for the investigation of transport selectivity. In addition, activity of both trypsin and chymotrypsin can be measured by ester hydrolysis, so that measurements of enzyme activities in secretion are based on the hydrolysis of similar bonds in reactions with the same stoichiometry<sup>4,5</sup>, which helps to decrease error in the comparison of the content of the two enzymes in secretion.

The duodenal hormone, pancreozymin, causes a massive release of granules containing protease from pancreatic acinar cells into duct lumina<sup>9</sup>, but, on the other hand, its effect on protein synthesis is probably of minimal quantita-

Fig. 1. The effect of pancreozymin on output of activity of trypsin and chymotrypsin by a rabbit pancreas *in vitro*. The shaded area indicates a standard deviation about the T/Ct ratio mean for control experiments.

Fig. 2. The effect of methacholine chloride on output of activity of trypsin and chymotrypsin by a rabbit pancreas *in vitro*.

Table 1. EFFECT OF PANCREOZYMIN ON TRYPSIN/CHYMOTRYPSIN RATIOS OF RABBIT PANCREATIC SECRETION *in vitro*

Treatment	No. of experiment	Time after mounting (h)	Trypsin/chymotrypsin ratio $\pm$ S.D.
None	3	2	$7.0 \pm 1.2$
None	3	3	$6.6 \pm 1.1$
None	3	2	$6.1 \pm 0.6$
Pancreozymin	3	3	$15.8 \pm 6.0$

tive importance during the short time required to elicit zymogen release<sup>10</sup>. For this reason pancreozymin may be very useful for the investigation of zymogen transport without the difficulty caused by simultaneously varying significantly the rates of enzyme synthesis.

The *in vitro* rabbit pancreas preparation is also well suited for comparison of transport rates of exportable proteins, because trypsinogen to chymotrypsinogen ratios (T/Ct) in secretion are relatively constant and consequently the secretion of these enzymes relative to each other can be assessed with reasonable accuracy. The shaded area in Fig. 1 indicates one standard deviation about the ratio mean for control experiments ( $n=9$ ). Differences in the ratios from the second to the fifth hourly collections were not significant and the various hourly values were pooled to give the mean for the experiment ( $n$ ).

When pancreozymin (6.0 Ivy dog units of 'Ceeekin' (Vitrum)/100 ml. of water in the bath) was added to the solution bathing the pancreas, a great enhancement in secretion of trypsinogen (output) was observed while chymotrypsinogen in secretion was only slightly elevated (Fig. 1). As a result, the T/Ct ratio of secretion more than doubled (see Table 1) ( $P < 0.05$  (control and experimental preparations were compared for ratio differences from hours 2 to 3 using Cochran's approximation of the Behrens-Fisher test). If secretion of protein by the pancreas was not selective, then the T/Ct ratios would not have changed. T/Ct ratios of rabbit pancreatic secretion *in vivo* are quite variable, but a similar enzyme selectivity was observed in three anaesthetized rabbits ( $\Delta$ T/Ct: +22.0, +12.5, +5.9).

The presence in secretion of an inhibitor of trypsin or a possible chymotryptic inhibitor could alter the activities

### Soluble vs. Granular Transport

### Homogeneous Granule Competition

### Soluble Enzyme-Membrane Specificity

Fig. 3. Some transport pathways that could produce "enzyme-specific secretion" by pancreatic acinar cells.

of the enzymes and therefore had to be accounted for. To assay for enzyme inhibition we added known amounts of purified trypsin or chymotrypsin to samples of juice in which the enzymes were left as proenzymes and looked for diminished activity of the added enzyme standards. No diminution in the activity of the chymotrypsin standard was observed in any of the experimental conditions and alterations in the activity of the trypsin inhibitor could not account for the changes in ratio produced by pancreozymin.

A cholinergic stimulant, methacholine chloride, was also added to the *in vitro* medium (0.8 mg/100 ml. of fluid). Methacholine was a potent stimulus of the secretion of enzyme *in vitro* and the output of both trypsinogen and chymotrypsinogen increased after methacholine was added to the bath. The T/Ct ratio was more variable than in controls, but there was no consistent difference in the enzyme ratio between methacholine-treated and control preparations ( $\Delta T/Ct = +2.1 \pm 4.0$  S.D.;  $n = 3$ ).

If the selective enzyme secretion in these experiments was not the result of changes in the relative velocities of synthesis of trypsinogen and chymotrypsinogen, then some aspect of enzyme transport was modified. An altered intracellular transport preference probably cannot explain the phenomenon, for the amount of enzyme movement from the ribosomes into secretory granules would probably be quite small in comparison with the amount of enzyme "released" from the cell on stimulation with pancreozymin. This would be even more so in zymogen-filled acinar cells of rabbits which had been fasted for 18–22 h before the experiment. Selectivity, therefore, most likely occurs in the "release" phase or in transport of protein from the zymogen granules or cytoplasm into duct lumina. Such an effect could be explained in several ways.

For example, there could be competition for plasma membrane sites by zymogen granules containing different enzymes, although what the basis of such a distinction could be is not clear. An alteration in the rates of enzyme secretion from within zymogen granules as compared with secretion of enzymes free in the cytoplasm could give the observed results if the T/Ct ratio in the zymogen granules were different from that in the cytoplasm (Fig. 3). Some exportable enzyme is present apparently free in the cytoplasm<sup>11</sup>, although we do not know if these enzymes can be secreted directly or must be incorporated into secretory granules first. Yet another possibility is that the enzymes themselves compete for transport sites on either the plasma or zymogen membranes or both with one enzyme being favoured over the other. It remains to be seen whether or not this phenomenon is just an oddity or has more general implications concerning the ways in which large molecules are secreted.

## Conversion of Non-immune Cells into Antibody-forming Cells by RNA

by

EDWARD P. COHEN

Institute of Microbiology,  
Rutgers, the State University,  
New Brunswick, New Jersey

RNA extracted from the spleens of mice immunized with sheep red blood cells converts some spleen cells from non-immunized mice to form antibody. The substance responsible for this conversion is RNA rich material with a coefficient of sedimentation between 8S and 12S. There may be specific recognition sites for this RNA on a few competent recipient cells which respond by producing antibody.

EXTRACTS of ribonucleic acid from macrophages exposed to antigen stimulate the formation of antibody in lymph node cultures<sup>1,2</sup>. The nature of the transfer substance is at present being investigated by several research groups. Askonas and Rhodes<sup>3</sup> and Friedman *et al.*<sup>4</sup> have suggested that antigen is involved; Fishman and Adler (personal communication) separated the reactivity of RNA-antigen complexes from RNA alone.

Previously, we reported that RNA extracted from the spleens of mice immunized with sheep red blood cells converted a small proportion of non-immune mouse spleen cells to form sheep cell haemolysins<sup>5,6</sup>. In general, sheep cell haemolysins are IgM (19S) globulins. The reaction was specific for RNA from immunized mice and was non-competitive over a wide range of RNA concentrations. The active material was very sensitive to ribonuclease, but was resistant to pronase, trypsin, and amylase. In this report, we present additional characteristics of the system: the effect of 5-fluoro-2-deoxyuridine; the kinetics of RNA synthesis after exposure to antigen; and the inhibitory effect of partially degraded RNA from mice immunized to

sheep red blood cells on the conversion of normal cells by non-degraded RNA.

RNA was extracted from the spleens of mice on day 4 after intraperitoneal injections of 0.1 ml. of a 25 per cent suspension of sheep red blood cells on days 0 and 3. The hot phenol technique<sup>7</sup> was followed as previously described<sup>8</sup>. Briefly, the spleens were quickly frozen on dry ice and then disrupted by high speed homogenization in an acetate: phenol mixture containing bentonite, sodium dodecyl sulphate, and 8-hydroxyquinoline. After precipitation and several washes with 66 per cent ethanol, the RNA was separated by sucrose density gradient centrifugation. Previous experiments indicated that the active RNA was in the 8–12S fraction. RNA from the 8–12S fraction was added to 0.3 molar sodium acetate and precipitated with two volumes of absolute alcohol. The RNA was used on the day it was isolated.

Spleen cells were obtained as indicated from immunized NIH or B6A.F1 mice by teasing the spleens apart in cold medium 199 (ref. 8). The cells were dispersed further by gentle pipetting, allowed to settle briefly and the super-

natant consisting mostly of single cells was removed. The nucleated cells were counted in a haemocytometer.

The number of cells producing sheep cell haemolysins was determined by the plaque assay method described by Jerne<sup>9</sup>. Medium 199 was added to purified agar to a final concentration of 0.7 per cent immediately before use. It was maintained at 45° C in 2 ml. portions. Each agar tube was allowed to cool to 38°–40° C before the addition of 0.1 ml. of 10 per cent sheep red blood cells (SRBC) followed by up to 0.5 ml. of spleen cells for analysis. After mixing, the agar-cell suspension was quickly poured over 0.7 per cent agar-199 base in a 10 cm Petri plate. The preparation was incubated at 37° C 2–3 h before the addition of 1.5 ml. of 25 per cent guinea-pig complement. After incubation for a further 30 min the plates were ready for examination. Plaques, which were frequently small, were identified under low power ( $\times 10$ ) magnification. Each plaque was symmetrically round and had an identifiable cell at its centre.

The pellet obtained after precipitation and high speed centrifugation of the 8-12S fraction was dissolved in medium 199. To minimize variation between individual animals, a pool of cells was prepared from the spleens of non-immunized mice. After the cell count had been determined, portions from this pool were suspended in 1.0 ml. medium 199 and were incubated after addition of 1.0 ml. RNA for 15 min at 37° C in a water bath equipped with a shaking device. Equal portions of cells were taken as controls from the same pool, and were incubated in medium 199 for the same period in the same total volume. After incubation, the cells were plated without further treatment and the proportion of cells producing sheep cell haemolysin was determined as previously described.

5-Fluoro-2-deoxyuridine (FUDR) acted as an adjuvant when administered in small doses<sup>10</sup> with antigen. A greater proportion of spleen cells forming haemolysins was found in mice injected with 1.0  $\mu$ g FUDR and SRBC than in mice receiving the same number of SRBC alone (Fig. 1). In an analogous manner, a greater proportion of spleen cells from non-immunized mice receiving 1.0  $\mu$ g FUDR (without SRBC) was converted to antibody-forming cells by RNA than were the same number of spleen cells from non-immunized mice not injected with FUDR (Fig. 2). No significant increase in the proportion of cells spontaneously forming haemolysins was found in animals receiving this dose of FUDR.

The rate of incorporation of uridine labelled with tritium into RNA was accelerated in the spleens of mice after injections of SRBC (Table 1). As early as 2 h after the

Fig. 1. Plaque formation in the spleens of mice after FUDR and SRBC. *NIH* mice were injected intraperitoneally with 0.1 ml. 25 per cent SRBC with (●) or without (○) 1.0  $\mu$ g FUDR. At varying times thereafter, the proportion of plaque-forming cells (PFC) in a pool from the spleens of four mice was determined by the plaque assay method. Groups exposed to FUDR and SRBC had significantly higher numbers of plaques than those exposed to SRBC alone  $P < 0.01$ . (Note. Variations from experiments reported in Tables 3 and 4 and Fig. 1 were not different from one another, hence the pooled estimate has been used throughout. We thank Dr. H. Andrews for performing the statistical analyses.)

Fig. 2. Plaque formation by spleen cells from mice receiving FUDR (without antigen) after incubation with RNA from immunized mice. *NIH* mice, a non-inbred strain, were injected with 1.0  $\mu$ g FUDR (control mice were not injected). At varying times thereafter, 100  $\times 10^6$  cells prepared from their spleens were incubated with RNA extracted from the spleens of mice 4 days after immunization with SRBC. RNA from the 8-12S fraction of a sucrose density gradient was used. After incubation, the proportion of plaque-forming cells was determined by the plaque assay method. The points, averages of two independent determinations, represent the total number of plaque-forming cells found minus the number of plaques forming spontaneously in the same number of cells not incubated with RNA. The solid horizontal line represents the average number ( $\pm$  S.D.) of spleen cells from non-immunized mice not injected with FUDR converted to form antibody by RNA from the 8-12S fraction.

intravenous injection of antigen into *B6A/F1* mice (control mice received isologous mouse red blood cells) RNA synthesis was increased as measured by the specific activity of total splenic RNA after a 60 min pulse of tritium-labelled uridine before the animals were destroyed. This accelerated rate of incorporation of precursor occurred over a period of 72 h, but by 96 h after the injection of antigen it had returned to control levels. Separation of the RNA by density gradient centrifugation revealed a progressive increase in the rate of labelling of the 8-16S fraction (Fig. 3). These data confirm results recently reported by Mach and Vassalli<sup>11</sup>.

Table 1. RNA SYNTHESIS IN THE MOUSE SPLEEN AFTER ANTIGEN

Hours after antigen	Specific activity immune/control	Antibody-forming cells per 10 <sup>6</sup> spleen cells
2	1.64	0.9
24	1.12	0.8
72	2.47	54
96	1.02	470
120	1.02	112

*B6A/F1* mice received 0.1 ml. of 25 per cent SRBC intravenously, control mice received isologous mouse cells intravenously. Sixty minutes before they were killed, each mouse received 50  $\mu$ c. of tritium-labelled uridine in 0.1 ml. and the specific activity of the RNA extracted from the spleens was determined by counting in a liquid scintillation counter.

RNA from the 8-12S fraction was found to be relatively resistant to digestion by ribonuclease when this was attempted either in medium 199 or in physiological salts (Earle). In the presence of calcium (II) and magnesium (II), RNA has a higher degree of secondary structure<sup>12</sup>, which is reflected in the hyperchromicity obtained after heating RNA from the 8-12S fraction (Fig. 4). More biological activity remained after addition of ribonuclease when RNA was dissolved in medium 199 than when ribonuclease was added to RNA dissolved in sodium chloride and EDTA (Table 2). As measured by density gradient centrifugation, more large molecular weight components remained after RNA from the 8-12S fraction was treated with ribonuclease in physiological salts than in sodium chloride and EDTA.

Because the reaction was non-competitive, we postulated<sup>5,13</sup> that recipient spleen cells probably had specific

Fig. 3. Patterns of uridine incorporation into RNA after antigen. RNA was extracted from the spleens of mice at varying times after the intravenous injection of 0.1 ml. of 25 per cent SRBC and an intravenous injection of 50  $\mu$ c. tritium-labelled uridine in 0.1 ml. 30 min before the animals were killed. After separation of the total cellular RNA by density gradient centrifugation, the specific activity of each fraction was determined by precipitation with trichloroacetic acid before collection on membrane filters and by counting in a liquid scintillation counter.

Fig. 4. Hyperchromicity of RNA from the 8-12S fraction after heating. About 160  $\mu$ g of RNA from the 8-12S fraction was dissolved either in medium 199 or in 0.15 molar sodium chloride containing  $2 \times 10^{-4}$  molar EDTA. Optical density at 260 m $\mu$  was determined in a Zeiss spectrophotometer equipped with a flow through heating device. ○, — Calcium (II) and magnesium (II); ●, + calcium (II) and magnesium (II).

recognition sites for RNA or an RNA-antigen complex. To test this hypothesis, two series of experiments were performed in an attempt to saturate these sites before the addition of biologically active material. Previous incubation of non-immune mouse spleen cells with minimally digested RNA from the 8-12S fraction of immunized mice inhibited the conversion of potentially active cells when non-digested RNA was later added (Table 3). This reaction was specific because previous incubation of non-immune spleen cells with digested or non-digested RNA from animals immunized with *Escherichia coli* or diphtheria toxoid failed to inhibit the conversion of cells to form sheep cell haemolysins by RNA from mice immunized with SRBC (Table 4).

\* Enriched RNA, RNA obtained from the 8-12S fraction.

† Immune RNA, RNA extracted from the spleens of mice immunized with sheep red blood cells.

‡ B6A.F1 mice were injected intraperitoneally with 0.1 ml. of 25 per cent SRBC on days 0 and 3; RNA extraction was on day 4. After centrifugation in a sucrose gradient (7-20 per cent) the RNA in the 8-12S fraction was adjusted to 0.3 molar sodium acetate and was precipitated with two volumes of absolute alcohol. One portion of the precipitate was redissolved in medium 199, another portion in 0.15 molar sodium chloride containing  $2 \times 10^{-4}$  molar EDTA. Ribonuclease (boiled before use) was added to a final concentration of 0.018  $\mu$ g/ml. to that portion dissolved in sodium chloride and, after incubation, the digest was incubated with  $150 \times 10^6$  non-immune spleen cells in medium 199 for 15 min at 37°C with shaking. At the end of this period, an aliquot of the portion of RNA dissolved in medium 199 was added and the mixture incubated for an additional 15 min.

Control incubations were for 30 min and  $100 \times 10^6$  cells from each group were examined.

Earlier, my colleagues and I reported that RNA extracts from mice immunized with sheep red blood cells converted a small proportion of non-immune cells into cells producing sheep cell haemolysins. The phenomenon, although consistent in replicate tests, was complicated by the fact that only a rather small proportion of non-immune spleen cells responded to the RNA extracts. About fifty in  $10^6$  cells responded, which means, of course, that in experiments in which the number of spontaneously appearing plaques in cell populations from non-immunized animals exceeds fifty in  $10^6$  cells (background), the total number of plaques found after exposure to RNA may be less than double the background. This problem, however, may not be technical in nature because a series of recent investigations indicated that the proportion of spleen cells competent to respond to a given antigen is limited<sup>14,15</sup>. These estimates were supported experimentally by Nakano and Braun<sup>16</sup>, who found a non-random distribution of mouse spleen cells responding to heterologous red cells in pieces of mouse spleen prepared and analysed after immunization. They associated these observations with a limited number of clones capable of forming antibodies to a given antigen. Friedman and Young<sup>17</sup> adapted the Jerne plaque assay system to an analysis of spleen slices and provided direct support for this conclusion by demonstrating the presence of a limited number of foci of cells producing sheep cell haemolysins in the spleens of immunized mice. Both

$S_d = 0.050$ ,  $L.S.D. = 0.110$ .

$P < 0.01$  for groups incubated with immune RNA and non-immune cells alone (see Note to Fig. 1).

\* Enriched RNA, RNA obtained from the 8-12S fraction.

† SRBC immune RNA, RNA extracted from the spleens of mice immunized with 0.1 ml. of 25 per cent sheep red blood cells.

‡ Heterologous immune RNA, RNA extracted from the spleens of mice immunized with  $10^6$  heat killed *E. coli* or 0.1 ml. diphtheria toxoid as indicated.

§ B6A.F1 mice were injected intraperitoneally with 0.1 ml. of 25 per cent SRBC, or with  $10^6$  heat killed *E. coli* in 0.1 ml., or with 0.1 ml. diphtheria toxoid (Diffo) as indicated on days 0 and 3; RNA extraction was on day 4. Experimental conditions were as described in previous tables.

Nakano and Braun, as well as Friedman and Young, showed that separate and distinct clones responded to different antigens. The number of presumed stem cells and the number of clones derived therefrom, with the capacity to respond to sheep red blood cells, must be limited even in the case of a complex antigen as sheep red blood cells.

Despite the limited number of stem cells, the proportion of potentially competent cells derived from them might be increased without the production of antibodies by certain adjuvants administered without antigen. The results obtained with FUDR, administered without antigen (Fig. 2), are consistent with this hypothesis.

Normally the immune response is accompanied by the division of antibody-forming cells<sup>18</sup>. It has been reported that RNA from immunized animals causes a generalized stimulation of cell division in lymphoid tissue<sup>19</sup>. This may explain the observation that the peak increase in the proportion of cells from mice treated with FUDR converted by RNA (Fig. 2) preceded by 2 days the maximum proportion of antibody-forming cells after the injection of antigen (Fig. 1).

What is the nature of the converting or activating substance in the RNA extracts from immunized animals? This material(s) originates either in macrophages or in lymphocytes or both. If it originates in macrophages, and the strain specificity of the response might support this supposition (Mithison (personal communication) found that the activation of antibody production by lymphocytes from non-immunized mice after exposure to macrophages from immunized mice was strain specific), it is probably either pure RNA or an RNA-antigen complex. (Despite the extraordinary sensitivity of the active material to ribonuclease, and its resistance to inactivation by proteolytic enzymes and amylases, the participation of a trace of antigen cannot definitely be ruled out. On the other hand, the finding of recognizable antigen fragments in active RNA preparations by others<sup>4</sup> does not establish the necessary participation of these fragments in the responses which we investigated.) The specific blocking of the reaction by preparations treated with enzyme, therefore, may represent an interference with the recognition by lymphocytes either of a polynucleotide sequence or of an antigen. Alternatively, if the activating substance originates in lymphocytes, then it probably is a messenger RNA and the blocking reaction might represent a specific interference with the transfer of messenger from lymphocyte to lymphocyte. In either event, the data strongly

suggest the presence of specific recognition sites on the competent recipient cells.

The presence of specified binding sites on recipient lymphocytes is predictable from a model of antibody formation which requires the co-operative efforts of two cell types for antibody formation<sup>13</sup>. This model, akin to intercellular regulations by hormones<sup>20</sup>, postulates that macrophages transfer an activating or informative material to a small number of competent lymphocytes. To react specifically to the stimulating material, these recipient cells must have recognition sites for the product of the macrophages. Moreover, if the transfer material is to "find" the few competent recipient cells, it must be produced in excess. This expectation is in agreement with our finding that RNA from the 8-12S fraction of the gradient, which was exclusively active in converting cells to form antibody<sup>6</sup>, is synthesized at an accelerated rate within 2 h after administration of antigen.

Investigations are in progress to define further and to elucidate the precise role of the active material in the immune response.

We thank Dr. W. Braun for his help in this work, which was supported by U.S. Public Health Service grants.

## Death of *Saccharomyces cerevisiae* in Aerosols

by

J. D. CHAPMAN

S. J. WEBB

The addition of inositol to the yeast *Saccharomyces cerevisiae* protects the yeast—when suspended in air—against death from desiccation, ultra-violet light and X-rays.

PREVIOUS work has shown that the rate at which deaths of bacterial cells and viruses occur in aerosols is strongly influenced by the relative humidity of the air in which the micro-organisms are suspended. Not only does the relative humidity of the air alter the response of micro-organisms to desiccation alone, but to both ultra-violet light and X-rays. In general, aerosolized bacterial cells and viruses are more resistant to desiccation and ultra-violet light

when they are treated at relative humidities above 60 per cent but show their maximum sensitivity to X-rays when irradiated in air above 70 per cent relative humidity. In addition, the vitamin *i*-inositol has been shown to protect air-borne bacteria and viruses against damage caused by desiccation alone as well as by ultra-violet light and X-rays. As a result of these investigations, it was suggested that the deaths of micro-organisms in aerosols from desiccation

and ultra-violet light resulted from the removal and re-orientation of water molecules associated with the structure of large conjugate macromolecules. It was assumed also that many of the indirect effects of X-rays were caused by the ionization of these structural water molecules rather than free water<sup>1</sup>. The vitamin *i*-inositol possesses six hydroxyl groups on a cyclohexane nucleus potentially capable of forming hydrogen bonds similar in strength and structure to those formed by water molecules. The protective action of this compound was therefore considered to result from the ability of its hydroxyl groups to replace structural water and from the stability of its cyclohexane nucleus. This compound was found to prevent the inactivation of intracellular vegetative phages and the lysis of lysogenic bacteria when cells were desiccated and irradiated with ultra-violet light. In addition, in the concentrations required to afford protection to cells, *i*-inositol has been shown to inhibit protein synthesis, apparently by preventing the manufacture of specific mRNA<sup>2</sup>. The latter finding suggested that inositol combines with a molecule responsible for the coding of mRNA and it is thought that this combination renders the molecule more stable to desiccation, ultra-violet light and X-rays. In earlier work it was suggested that the reason why some microbial cells were more able than others to withstand desiccation and irradiation was because they contained higher concentrations of compounds similar to *i*-inositol. It seemed pertinent therefore to test this assumption through an investigation of the behaviour of a cell known to contain naturally large amounts of *i*-inositol. It is the purpose of this article to report findings with such a cell, the yeast *Saccharomyces cerevisiae* X841, supplied by R. K. Mortimer, of the University of California, Berkeley.

Fig. 1. The effect of relative humidity and inositol on the survival of *Saccharomyces cerevisiae* in aerosols.

Cells of *Saccharomyces cerevisiae* were grown on a wrist-action shaker for 48 h at 30° C in 200 ml. of Sabouraud liquid medium. The culture was removed in aliquots of 50 ml. and the cells washed once in sterile demineralized water by centrifugation. They were then resuspended in 10 ml. of demineralized water or a 5 per cent solution of *i*-inositol in water. The whole suspension was then transferred to a collision spray and the cells atomized

into a rotating drum<sup>1</sup> pre-set to a given level of relative humidity. Alternatively, aliquots of 1.0 ml. were deposited on 47 mm 'Millipore' filters. The filters plus the layer of cells, approximately ten to twenty cells thick, were then placed in a circular chamber and a steady flow of air of a given relative humidity passed over them. Approximately 2 h were required before the air in the chamber reached the desired level of relative humidity after the entry of the damp filters. The cells on the filters or those in the aerosol were irradiated with an X-ray tube operated at 200 kV and 20 m.amp to give a dose rate of 655 r./min at the positions of the filters and approximately 16 r./min in the drum. Following irradiation, the cells on the filters were washed off with 10.0 ml. of 0.85 per cent saline, serially diluted and 0.2 ml. of each dilution was plated into a medium consisting of 1 per cent yeast extract, 1 per cent peptone, 2 per cent dextrose and 2 per cent agar. Samples from the aerosol were taken using a liquid impinger<sup>1</sup> operating at 9.0 l./min and containing 10.0 ml. of saline. The cells were serially diluted in saline and plated as for those on filters. The extent of radiation damage was measured as a difference between the number of cells surviving desiccation alone and those remaining after desiccation and irradiation.

Fig. 2. The effect of relative humidity and inositol on the exponential death rate constant calculated from the slopes of the survival curves. ×, From water; ○, from inositol.

The initial experiments were conducted with cells deposited on filters. This was done because earlier work with the yeast had suggested that a dose of X-rays sufficient to produce cell deaths could not be delivered into the aerosol drum within a practical length of time. It soon became clear, however, that at humidity levels of below 75 per cent, numbers of the yeast cells died because of desiccation alone so that, with the long periods of time required to establish an equilibrium of relative humidity, variations in viable cell numbers following desiccation became greater than the variation caused by radiation. The experiments with the filters were therefore confined to values of relative humidity between 75 and 95 per cent. Within this range of humidity, few cells died as a result of the desiccation and the deaths which resulted from X-radiation appeared to follow a sigmoidal relationship with dose (Fig. 4). To destroy

approximately 90 per cent of the cells with X-rays required a dose of 70 kr. and the radiation sensitivity did not alter with changes in relative humidity between 75 and 95 per cent. Attempts to demonstrate a protective effect of *i*-inositol on the cells on filters against both drying and radiation damage failed. These results are in agreement with earlier findings with multiple layers of bacterial cells deposited on filters<sup>1</sup>. Related investigations on the effects of X-rays on air-borne bacteria revealed that such cells were unexpectedly sensitive to irradiation<sup>3</sup>. It seemed reasonable, therefore, to conduct experiments with aerosols of yeast cells first to determine whether they were more sensitive to X-rays than cells on filters and second to test the effects of relative humidity and inositol on their sensitivity.

Fig. 3. The survival of *Saccharomyces cerevisiae* in aerosols with and without exposure to 200 kVp. X-rays at an average exposure rate of 16 r./min in the presence or absence of inositol.

The results obtained with the unirradiated (dark) aerosols of yeast cells demonstrated that they were extremely sensitive to drying. At relative humidities above 85 per cent, few deaths occurred, but as the relative humidities were lowered from 85 to 60 per cent, large numbers of cells died and the rate at which the deaths took place increased as the relative humidities decreased (Fig. 1). A large number of experiments were carried out of which only a few typical results are shown. At relative humidities below 85 per cent the rate of deaths of the cells appeared to follow two phases, an initial rapid rate of deaths taking place during the 10 min required to generate the aerosol and collect the first sample, followed by a period in which subsequent deaths took place more slowly and followed an exponential function with time. This initial rapid death rate is shown in Fig. 1 by the number of viable cells/l. of air in the initial aerosol samples. It can be seen that both the initial and secondary rate of deaths increased rapidly as the relative humidity was decreased. These findings were somewhat surprising, because they indicated that the inositol present naturally in the cells afforded them little protection against desiccation in aerosols. It was pertinent then to determine whether additional inositol would preserve their viability. This proved to be the case, because in the presence of inositol few deaths occurred above 60 per cent relative humidity and the rate at which they did so below this level was con-

siderably reduced (Fig. 1). In addition, the compound prevented both the initial and secondary deaths. Because the rates of deaths in both phases were dependent on the relative humidity and both were slowed by inositol, it is assumed that the mechanisms responsible for death in each case have at least one important factor in common. In Fig. 2, the exponential death rates obtained from individual experiments are plotted against relative humidity. The presentation of the results in this fashion shows clearly the marked increase in sensitivity of water-atomized cells as the relative humidity decreases below 85 per cent. This behaviour is different from that observed with bacterial cells<sup>1</sup> where the death rate remained approximately constant as the relative humidity was lowered from 90 to about 70 per cent and then rapidly increased as the relative humidity dropped to 40 per cent. The fact that added *i*-inositol almost completely preserved the viability of the dried cells down to 60 per cent relative humidity and offered considerable protection to the cells below this level (Figs. 1 and 2) suggested that it preserved the yeast cells through a mechanism similar to that by which it prevented damage to bacterial cells and viruses. At the same time, because the lipid-bound inositol naturally present in the yeast cell did not offer protection, it was reasonable to conclude that in order to exercise its protective ability, the inositol must be free.

Fig. 4. The survival of *Saccharomyces cerevisiae* as a function of exposure to X-rays using aerosolized and filter-mounted cells. The death rate from drying has been subtracted to give the net effect of the radiation.

It has been shown in earlier work that bacterial cells both in aerosols<sup>3</sup> and on filters<sup>4,5</sup> displayed their maximum sensitivity to X-rays at relative humidity greater than 70 per cent. In view of these findings and because of the long periods of time required to deliver a given dose of X-rays into the drum, investigations into the effect of X-rays and inositol on air-borne yeast cells were carried out only at relative humidity values above 80 per cent. From the results there were two significant findings. First, yeast cells in aerosols were apparently completely protected from X-ray damage by added inositol (Fig. 3) and, second, air-borne yeast cells were very much more sensitive to X-rays than those treated on filters (Fig. 4). In Fig. 4 the results are shown as plots of survival versus dose, for both filter-dried and aerosolized cells. It can be seen that for the cells irradiated on filters the curve is of the sigmoidal (or multi-hit) type, whereas for the aero-

solized cells it is of the exponential (or single-hit) type (Figs. 3 and 4).

The foregoing results obtained with yeast cells in aerosols were similar to findings with bacteria and viruses both from the standpoint of their increased X-ray sensitivity and the action of *D*-inositol. The work suggests that natural inositol in the cell does not appear to endow it with added stability towards desiccation or X-rays. At this time it is not known why aerosolization changes the response of

microbial cells to radiation or why aerosolized cells are more easily protected by inositol than those desiccated on filters.

## Apparent Phytochrome Synthesis in *Pisum* Tissue

by

DAVID T. CLARKSON

WILLIAM S. HILLMAN

Biology Department, Brookhaven National Laboratory, Upton, New York

The increase of phytochrome in pea plants which have been irradiated with red light and then returned to the dark is related to the initial decrease of phytochrome (after irradiation) below a certain critical amount. The increase may result from the re-establishment of photo-reversibility in a fraction of the phytochrome present in a non-reversible pool.

THE phytochrome system almost certainly acts as a photoreceptor controlling the growth and flowering of plants grown in the light<sup>1</sup>. Most attempts to link phytochrome transformations with physiology, however, have been made on etiolated seedlings<sup>2-5</sup> because green tissues<sup>6</sup> do not readily lend themselves to work with the dual wavelength ratiospectrophotometer. Transformation investigations with etiolated seedlings that have been briefly illuminated with red light and returned to darkness have shown that the far-red-absorbing species of the pigment is labile<sup>2-5</sup>. Depending on the tissue examined, 50-80 per cent of the total phytochrome is destroyed, or at least rendered spectrophotometrically undetectable, as a result of the brief initial illumination. It seems likely, therefore, that in plants subjected to natural illumination the phytochrome in the tissue will be rapidly reduced to a very low concentration unless an additional mechanism is brought into operation. Some of the phytochrome might be conserved if a fraction of it were light-stable, or an adequate concentration might be maintained if synthesis of new phytochrome reached an equilibrium with the destruction of far-red-absorbing pigment. So far there is one reported instance of phytochrome which is light-stable<sup>6</sup> and none concerning phytochrome synthesis in non-etiolated tissue. Increases in total phytochrome accompanying growth of etiolated seedlings have been described in two reports<sup>4,5</sup>.

We have observed changes in the amount of phytochrome in pea plants that have been illuminated for various lengths of time with red light after an initial growth period of 7 days in darkness. Estimations of phytochrome were made with a dual wavelength spectrophotometer, using an external actinic light source and filters for the photoconversion of the pigment. The standard sample of tissue assayed consisted of 200 mg of segments cut from the epicotyl hooks of approximately twenty plants of *Pisum sativum* cultivar 'Alaska' (pea). The tissue was packed into metal cuvettes 6 mm in diameter to form a bed of material 1 cm in depth. The plant growth conditions, the *in vivo* assay, and the light sources and filters are described in detail in earlier publications<sup>2,3,7</sup>. Extracts of phytochrome were prepared by grinding in a chilled mortar 2 g of hook segments with 2 ml. of buffer and a small quantity of sand washed with acid. The resulting homogenate was filtered through glass wool and the filtrate centrifuged at 10,000*g* for 15 min. Two millilitres of the clarified extract was layered on the top of a 'Sephadex G-50' column which had been pre-equili-

brated with the extraction buffer, and eluted with the same buffer. Fractions of 2 ml. were collected and 1 ml. was taken from each fraction and run on to a 1 cm bed of finely divided, anhydrous calcium carbonate<sup>8</sup> in cuvettes of 1 cm diameter. The buffer solution was made from 0.3 molar potassium monohydrogen phosphate and potassium dihydrogen phosphate, pH 7.8, with 0.002 molar ethylenediamine tetraacetic acid dipotassium salt and 0.3 per cent mercaptoethanol. All the steps were conducted at 2° C under dim green safelights.

When pea plants grown in the dark, or excised segments of pea stems grown in the dark, are illuminated briefly with red light and then returned to darkness for 6-8 h, the total phytochrome falls to 45-50 per cent of the concentration in non-irradiated control tissue<sup>7</sup>. After 6 h all the remaining pigment is in the red absorbing form, and because this form appears to be stable the total phytochrome remains constant for at least 24 h. If the tissue, however, is pretreated with a succession of exposures to red light which last 15 min (so that the phytochrome falls to a low concentration) and then returned to darkness, the total phytochrome does not reach a constant concentration, but actually increases. This phenomenon is illustrated in Fig. 1. In this discussion, the term "new" phytochrome refers to the increase in total phytochrome above the minimum level measured after the light pretreatment. All the new phytochrome is of the form which absorbs red.

The values for the change in the change of the optical density ( $\Delta(\Delta O.D.)$ ) obtained by *in vivo* spectrophotometry are in part the results of amplification caused by dispersion of the measuring beam as it passes through the tissue<sup>8</sup>. It seemed possible that our findings were the result of increased light-scattering in the repeatedly illuminated tissue because of the formation of refractive bodies such as plastids or proplastids during the ensuing dark period. The increases observed *in vivo*, however, are matched by increases in extractable phytochrome (Fig. 2).

When light pretreatments were so arranged that the minimum phytochrome concentration in the tissue varied from 5 to 45 per cent of that in non-illuminated controls, it soon became apparent that significant increases in phytochrome in the subsequent dark period were observed only if the phytochrome fell below a certain critical concentration. So far the data suggest that the critical concentration is sharply defined at between 16 and 22 per cent of the initial concentration. Moreover, there is some indication that the amount of new phytochrome

Fig. 1. Phytochrome levels in hook segments given various light pretreatments. Values are percentages of those in plants grown in the dark at h 0. Red light treatments of 15 min duration started at times indicated by arrows. Terminal bud removed before light treatment. A, Dark control; B, one red exposure; C, four red exposures.

synthesized in a 24 h dark period following illumination is closely related to the amount by which the phytochrome falls below the critical concentration—an amount designated the critical deficit. It can be seen in Fig. 3 that the relationship between the critical deficit and the amount of new phytochrome appearing in a tissue is approximately linear. This relationship has the effect of equalizing the amount of phytochrome in tissues which have received different illumination schedules and have then been returned to darkness. For example, five light (dark) cycles of 15 min light and 1 h 45 min dark reduced the phytochrome concentration in samples of hook tissues to  $\Delta(\Delta O.D.) \times 10^3$  of 40.0/g, whereas three light (dark) cycles of 15 min light and 1 h 45 min dark reduced the level to 100.0/g; in a 24 h dark period following these

Fig. 2. Elution of phytochrome extracts from 'Sephadex G-50'. Each fraction was 2 ml. Samples were taken from tissue 24 h (A) and 2 h (B) after a pretreatment in which the tissue received four cycles of 15 min light, 1 h 45 min dark. Assay of the tissue *in vivo* taken for extraction: A,  $\Delta(\Delta O.D.) \times 10^3$  157.5/g; B,  $\Delta(\Delta O.D.) \times 10^3$  62.5/g.

schedules the phytochrome concentration rose to 160.0/g in each instance.

The onset of apparent phytochrome synthesis was dependent on time only to the extent that the rate of destruction of far-red absorbing pigment (which reduces the total phytochrome) governed the minimum time in which the critical concentration could be reached. By illuminating the plants with three different light-dark schedules we have been able to induce a similar critical deficit at 4, 6 and 24 h, and in each case the rate of appearance of new phytochrome was similar (Table 1).

Table 1. PHYTOCHROME LEVELS IN APICAL HOOK SEGMENTS AFTER VARIOUS LIGHT PRETREATMENTS

Light (dark) pretreatment	$\Delta(\Delta O.D.) \times 10^3/g$			
	h 0	h 2	h 6	h 8
4 cycles, 15 min light, 5 h 45 min dark	112.5	69.0	84.5	100.0
4 cycles, 15 min light, 1 h 45 min dark	135.0	74.0	105.0	120.0
4 h, red only	100.0	54.0	—	98.0

h 0 refers to the time immediately after the last and h 2 to a time 2 h after the last exposure to red light. Tissue cut from decapitated plants growing in vermiculite.

The cells in the tissue described here were mostly immature and were capable of appreciable increases in size<sup>9</sup>, whereas the cells at the base of the second internode matured rapidly after illumination with red light and so had a limited potential for further growth<sup>10</sup>. Samples of tissue from this latter region showed no apparent phytochrome synthesis when taken from peas which had received a light pretreatment which had induced synthesis in the hook region of the third internode. This result suggests that apparent synthesis is associated only with developing tissue. It has been possible, however, to separate synthesis from actual growth in hook segments. In these experiments 5 mm segments were cut from the stems of intact plants just before the fourth illumination in an inductive light schedule and placed in Petri dishes. The growth, apparent phytochrome synthesis and total protein content of control segments were compared with these characteristics in segments where cell expansion was inhibited by the inclusion of 2 per cent and 8 per cent mannitol in the standard incubation medium. Table 2 shows that these treatments did not significantly affect the appearance of new phytochrome even though 8 per cent mannitol almost completely inhibited segment elongation. Conversely, treatment of excised segments with  $10^{-4}$  molar naphthalene acetic acid inhibited the synthesis of new phytochrome without decreasing segment growth (Table 2). A more detailed account of this last, unexpected result, together with data on the effect of other inhibitors and growth regulators, will be published elsewhere.

Fig. 3. The amount of new phytochrome synthesized in apical hook segments in the 24 h following the last illumination as a function of the lowest level of phytochrome induced by illumination pretreatment.

Table 2. PHYTOCHROME SYNTHESIS IN EXCISED BOOK SEGMENTS INITIALLY 5 MM LONG TREATED WITH MANNITOL AND NAPHTHALENE ACETIC ACID

Treatment	Elongation (mm)	New phytochrome $A(\Delta O.D.) \times 10^3/g$	New phytochrome: protein $A(\Delta O.D.) \times 10^3/mg$ protein
Experiment P-42			
Control	3.98	30.0	1.48
2 per cent mannitol	1.68	42.5	1.85
8 per cent mannitol	0.40	27.5	1.10
Experiment P-40			
Control	4.70	55.0	2.61
$10^{-4}$ molar naphthalene acetic acid	4.91	12.5	0.63

Light pretreatment in both experiments consisted of four cycles of 15 min light, 1 h 45 min dark. Tissue excised from intact plants between light exposures 3 and 4 and then kept for 24 h in darkness in Petri dishes containing 10 ml. of 0.1 molar potassium dihydrogen phosphate and potassium monohydrogen phosphate buffer pH 6.3 plus 0.4 per cent sucrose, with and without additives indicated. Total protein determined by biuret assay as described by Briggs and Siegelman (ref. 4).

What is the nature of the process that we have called apparent phytochrome synthesis? Several facts make it seem unlikely that it represents *de novo* synthesis of the entire chromoprotein. The process is relatively insensitive to progressive excision of the tissue, and proceeds almost as rapidly in short apical segments as in detached entire epicotyls, and almost as well in the latter as in intact plants. In excised segments it is unaffected by the presence or absence of sucrose in the incubation medium, although this factor certainly limits growth. In addition, a preliminary survey indicates that concentrations of chloramphenicol and puromycin that strongly inhibit growth fail to inhibit the appearance of new phytochrome. Though conclusive data on this question will come only from studies on the incorporation of labelled amino-acids, these observations suggest no close relationship between *de novo* protein synthesis and apparent phytochrome synthesis.

The dependence of apparent phytochrome synthesis, whatever its precise nature, on the reduction of the phytochrome content below a critical concentration requires further consideration, even though this is necessarily speculative at present. It may be useful to postulate the existence of two fractions of phytochrome in the cell, only one of them being the usual, photoreversible fraction measured in the assay. The other fraction would be closely related but irreversible and thus unmeasurable. This irreversibility might be a result of binding, structural modification or even a disassociation of the holochrome into chromophore and protein. Such an irreversible or unmeasurable fraction of phytochrome has been proposed before<sup>2</sup> for other reasons. Though there is no direct evidence for it at all, it would provide a basis for two alternative explanations of the present results.

The first explanation suggests that the critical concentration is the point at which these two fractions of phytochrome are in equilibrium. In plant material grown in the dark and tissue which has received only one red light

exposure, the measurable phytochrome fraction is greater than the critical concentration and thus no synthesis is observed. When the phytochrome is brought below the critical concentration by repeated exposure of the tissue to red light, irreversible phytochrome is released or rendered photoreversible. The rate of release is dependent on the critical deficit. A second possibility starts with the assumption that apparent destruction of far-red absorbing pigment represents a step in the formation of the irreversible fraction. When the latter reaches a critical concentration, release or reconversion of the measurable form begins. In this scheme the necessity for the measurable phytochrome to be reduced below a critical concentration would only be an apparent one, the real prerequisite for apparent synthesis being the "destruction" of a sufficient quantity of far-red absorbing pigment.

With either scheme in operation it is predictable that at some point the rate of destruction of far-red absorbing pigment and the reappearance of new phytochrome from the irreversible fraction will reach equilibrium. Such a system might operate to maintain a constant concentration of phytochrome in the developing tissues of plants growing in the light.

The only other report of observations in any way comparable with these is that of Spruit<sup>11</sup>, who studied phytochrome transformations in pea plumules and concluded that synthesis of red absorbing pigment, rather than any reversion of far-red absorbing pigment to red absorbing pigment, followed a single exposure to red light. The tissue used included the leafy bud and thus contained appreciable amounts of protochlorophyll; though ingenious corrections for interference by this substance in the *in vivo* assay were made, it is by no means certain that they were successful. The very small amount of protochlorophyll in pea stem tissue has a negligible effect on phytochrome assays, and this effect should be eliminated by the extraction procedure.

This research was carried out at Brookhaven National Laboratory under the auspices of the U.S. Atomic Energy Commission. We thank Dr. A. O. Taylor for the stimulating suggestions which prompted this investigation. We also thank Miss Helen Kelly for assistance.

## Ray Thickenings in the Walls of Conifer Tracheids

by

J. L. LADELL

Ontario Research Foundation,  
Toronto

The walls of conifer tracheids tend to be thicker when they are adjacent to medullary rays. In most species the extent of thickening seems to be less in the late wood than in the early wood. Thickening tends to be more pronounced in older wood and in vigorous trees.

It has been observed that the tangential tracheid wall in a number of species of conifers tends to be thickened in the region of the ray crossings. Fig. 1 shows a radial microscope section of late wood in Douglas fir, *Pseudotsuga menziesii* (Mirb.) Franco, where it can be seen that the

tangential walls of the tracheids are thicker where they cross the two medullary rays than they are above, between, and below the rays. In transverse section the thickenings are apparent in the relative massiveness of the tangential tracheid wall in files that happen to flank

a ray in the plane of the section. This is illustrated in Fig. 2, which shows a transverse microscope section of red pine, *Pinus resinosa* Ait.

These thickenings in the region of the ray crossings, of which there appears to be no account in the literature, were first noticed by me some years ago in samples of *Pinus radiata* D. Don. from East Africa, the United Kingdom, and Canada, and in three species of podocarp, *Podocarpus gracilior* Pilger, *P. javanicus* Blume, and *P. macrophyllus* D. Don. Measurements on transverse sections showed that in the samples of *Pinus radiata* the tangential walls of tracheids in files lying alongside rays, that is, in the region of ray crossings, were on the average 18.4 per cent, 20.8 per cent and 20.3 per cent thicker than the tangential walls of tracheids in files not flanking rays. Corresponding values in the three species of podocarp ranged from 4.1 per cent to 9.8 per cent.

Fig. 1. Photomicrograph of a radial section of Douglas fir showing thickening of the tangential tracheid wall at the ray crossings. ( $\times c. 550$ .)

This has now been followed up by an investigation of a number of coniferous species. The results suggest that "ray thickenings", if they may be so called, are widespread in conifers, and that their relative size tends to increase from the pith outwards. The results also suggest that in certain species and in certain conditions the thickenings may make a significant contribution to the amount of cell wall substance present—thus influencing both the density of wood and its variability—and that they may be relevant to the behaviour of softwood fibres in the making of paper.

As in the earlier work, the measurements were made on transverse sections. On such sections the rays, because of their random distribution with reference to the vertical axis, are sectioned at various heights. Measurements of cell wall thickness in files contiguous to rays therefore give values which represent the average degree of thickening from top to bottom of rays, as opposed, for example, to the maximum degree of thickening such as could be obtained from radial sections.

Blocks for the preparation of transverse sections were taken, with no particular care as to their location, from hand specimens showing mature wood of the following species: balsam fir, *Abies balsamea* (L.) Mill, Douglas fir, *Pseudotsuga menziesii* (Mirb.) Franco, loblolly pine, *Pinus taeda* L., long-leaf pine, *Pinus palustris* Mill. and another southern pine of unknown species. A single transverse section, 20  $\mu$  thick, was cut from each block and was stained with safranin and mounted in Canada balsam. On each section a single ring was selected at random and in twenty successive "ray" files, that is tracheid files contiguous to rays, the mid-point thickness of the common tangential tracheid wall in the first five cells in the early wood and in the last five cells in the late wood was measured under a microscope at a magnification of  $\times 850$  and using an eyepiece scale. Similar measurements were made in twenty control files, which were taken to be the file next but one to the ray file under examination. If the control file itself was found to flank a ray, the nearest suitable file was selected. The file immediately adjacent to a ray file was always avoided, however, in order to reduce the possibility of any inter-file effect on cell dimensions resulting from the mechanics of pseudo-transverse division.

Fig. 2. Photomicrograph of a transverse section of red pine illustrating the relative massiveness of the walls of tracheids in files contiguous to a medullary ray. ( $\times c. 265$ .)

The average cell wall thickness in ray and control files is given in Table 1 with separate values, each based on 100 measurements, for early wood and late wood.

In order to arrive at an estimate of the amount of wood substance contributed by the ray thickenings, it was necessary to measure not only their size but also their frequency. The files between twenty-five successive rays in both the early wood and late wood of each ring were counted, and from the total of fifty counts the mean number of files between rays was obtained. From this value the ratio of ray to control files, expressed as a

Table 1. INCREASE IN TANGENTIAL TRACHEID WALL THICKNESS IN THE REGION OF RAY CROSSINGS

Species	Mean rings/in.	Position of sample in ring	Mean thickness—common tangential wall			Increase in wood substance due to thickenings	Increase due to thickening (%)
			Ray file ( $\mu$ )	Control file ( $\mu$ )	Difference as % of control (%)	Mean No. of files between rays ( $n$ )	
Balsam fir	5.8	E	3.64	3.53	+3.1	5.76	1.1
		L	7.97	7.24	+10.1		3.5
Douglas fir	14.2	E	4.77	4.28	+11.4	4.82	4.7
		L	12.62	11.61	+8.7		3.6
Loblolly pine	3.8	E	6.02	5.10	+18.0	7.14	5.0
		L	11.77	10.38	+13.4		3.8
Long-leaf pine	22.1	E	8.61	7.29	+18.1	6.52	6.6
		L	13.93	13.09	+6.4		2.6

		L	8.44	7.58	+11.3		4.7

E, Early wood; L, late wood.

percentage, was derived in the knowledge that, of the mean number of files between rays, two files were ray files. A relative measure of the additional wood substance as a result of the presence of thickenings was then calculated by multiplying the mean percentage thickening by the mean percentage frequency of ray files. The results of these calculations are given in Table 1 together with the data obtained on ray frequency.

To investigate variation from the pith outward, measurements were made in the 5 year and 125 year ring from the pith in a fast and in a slow grown black spruce, *Picea mariana* Mill. (B.S.P.) showing 27.7 and 37.0 rings/in. respectively, and in the 1 year and 6 year ring of a fast and of a slow grown red pine, *Pinus resinosa* Ait., showing 5.8 and 8.7 rings/in. No measurements were made in the early wood of the younger rings, but otherwise the procedure followed and the data obtained were the same as described above. The results are given in Table 2.

Finally, in a single randomly selected ring of the fast grown red pine, measurements were made in twenty ray and twenty control files of the thickness of the first and of the last common tangential tracheid wall in the ring and at six predetermined points in between. The results are shown in Fig. 3, where the mean thicknesses of the wall of tracheids in ray and control files are plotted separately against distance across the ring expressed as a percentage of the width of the ring.

thickenings tended to increase from the pith outwards. In one black spruce the percentage thickening in the late wood increased from 1.6 per cent in the 5 year ring to 13.1 per cent in the 125 year ring, and in the other tree the increase was from 5.2 per cent to 7.4 per cent. The increase over 6 years of growth in one of the red pine was from 23.8 per cent to 31.3 per cent and in the other from 6.4 per cent to 20.9 per cent. A comparison of values at different distances from the pith but in rings of the same age showed that the thickenings tended to become more pronounced with rate of growth. This was particularly marked in the red pine where the percentage thickening in the late wood of the 6 year ring was found to be 31.3 per cent in the fast grown tree but only 20.9 per cent in the slow grown tree. Similar results were obtained in the black spruce, with the 125 year ring giving late wood values of 13.1 per cent compared with 7.4 per cent in the slow grown.

Of the various genera examined, *Pinus* tended to show the most pronounced thickenings. A comparison of early wood values showed that the most pronounced thickenings occurred in the unidentified southern pine (18.4 per cent) followed by long-leaf pine (18.1 per cent) and loblolly pine (18.0 per cent)—values close to those obtained in the early work on *Pinus radiata* where values from 18.4 per cent to 20.8 per cent were obtained. In the late wood, red pine tended to display the most pronounced

Table 2. VARIATION OUTWARDS FROM THE PITH IN THE SIZE OF RAY THICKENINGS

		1	L	3.49	3.28	+6.4				1.5

E, Early wood; L, late wood.

Ray thickenings were found in the tracheids of all the species examined. The most pronounced thickenings observed were in the late wood of the fast grown red pine where the tangential walls of tracheids were found to be 31.3 per cent thicker in the region of ray crossings than they were elsewhere. The least thickening observed was 1.6 per cent in the late wood of the 5 year ring of the fast grown black spruce.

In all the species examined except red pine and balsam fir, the thickenings were more pronounced in the early wood than in the late wood. In Douglas fir, for example, the increase in cell wall thickness at the ray crossings was 11.4 per cent in the early wood compared with 8.7 per cent in the late wood, while in the long-leaf pine the increase amounted to 18.1 per cent in the early wood compared with 6.4 per cent in the late wood. In the two red pine and the balsam fir, on the other hand, where the increase in wall thickness was more pronounced in late wood than in the early wood, the differences were even more marked. In the fast grown red pine the ray thickenings in the late wood were relatively twice as massive as those in the early wood (31.3 per cent compared with 15.3 per cent), while in the balsam fir the percentage thickening in the late wood was 10.1 per cent compared with only 3.1 per cent in the early wood.

The data obtained from the black spruce and red pine given in Table 2 showed that the relative size of the

thickenings (20.9 per cent and 31.3 per cent) with loblolly pine next at 13.4 per cent. The late wood of long-leaf pine, however, gave the relatively low value of 6.4 per cent. It could be argued that the tendency for the thickenings to be more pronounced in the pines is the result of high growth rates, associated either with the innate vigour of the genus or, in the case of the southern pines, with a favourable environment, but some evidence against this is provided by the three samples of *Pinus radiata* from East Africa, the United Kingdom and Canada, examined in the earlier investigation. All three samples showed much the same degree of thickening at the ray crossings, although they were grown in widely differing environments.

In calculating the relative amounts of additional wood substance attributable to the ray thickenings it was assumed, with some support from casual observation, that the radial walls in ray file cells were thickened to the same extent as the tangential and, further, that ray and control file cells were the same size in cross-section—that their mean radial diameters would be the same was beyond question, while a series of measurements on selected samples gave no indication of significant differences in their tangential diameters.

The results of the calculations, listed in the last column of Tables 1 and 2, showed that in all but the red pine and balsam fir the relative contribution of the ray thickenings

to the amount of wood substance present tended to be greater in the early wood than in the late wood. Thus, in the unidentified southern pine the increase in the amount of wood substance attributable to the thickenings was calculated to be 7.7 per cent in the early wood and 4.7 per cent in the late wood. On the other hand, in the fast grown red pine the late wood value was double that calculated for the early wood, 10.4 per cent compared with 5.1 per cent. The increase in wood substance was found to increase both with age from the pith and with growth rate. For example, a comparison of late wood values showed that 6 years' growth in the two red pine resulted in an increase from 6.3 per cent to 10.4 per cent in one tree and from 1.5 per cent to 5.7 per cent in the other, while in these same trees both early wood and late wood values in the sixth ring from the pith were markedly higher in the fast grown than in the slow grown tree—5.1 per cent and 10.4 per cent as compared with 2.4 per cent and 5.7 per cent (Table 2). The relations in black spruce were similar but not so marked. These increases appear to be caused more by the progressive enlargement of the thickenings from the pith outwards, as discussed above, than to increases in the file:ray ratio, a ratio which appears to remain comparatively stable throughout the life of the tree. For example, the mean number of files between rays in one black spruce was found to be 6.12 in the 5 year ring and 5.84 in the 125 year ring, with corresponding values of 5.42 and 5.50 in the other tree. In both red pine the ratios were slightly reduced in the course of 6 years' growth, from 7.56 to 6.00 in one tree, and from 8.44 to 7.32 in the other. This relative constancy in the file:ray ratio, which is a measure of the relative number of ray crossings, is of some intrinsic interest. It is apparently maintained in spite of marked changes in the absolute frequency of rays. Data obtained in another investigation in which measurements were made on transverse sections from the 10 per cent height level in twenty black spruce trees showed the mean ratio of files to rays changed from only 5.9 in the 5 year ring to 7.6 in the 135 year ring, although the mean number of rays/mm of ring circumference in these same rings decreased from 10.8 to 5.4 (unpublished data). The average tangential width of the tracheids in these trees, however, increased from  $15.3\mu$  in the 5 year to  $24.5\mu$  in the 135 year ring, following the trend observed in a number of species of conifers<sup>1-5</sup>. The increase in the tangential width of tracheids accompanying the decrease in ray frequency provides a partial if superficial explanation for the relative consistency of the file:ray ratio as observed on transverse sections. It must be remembered, however, that the frequency of rays as measured on this plane is influenced by both the number of rays/unit of tangential area, which tends in conifers to decrease from the pith outwards, and by the height of the ray which tends to increase<sup>1-5</sup>, so that the underlying factors which affect the file:ray ratio are of a complex nature involving a number of dimensional relationships.

In conclusion, it may be said that the presence of ray thickenings provides some basis for Myer's<sup>9</sup> claim that from species to species "(wood) density is directly proportional to an increase in ray volume", although Weinstein<sup>10</sup> quotes unpublished results of Koehler *et al.* for ash and Sitka spruce that would appear to refute Myer's conclusion. Certainly it would appear that the thickenings may in some circumstances exercise an appreciable effect on the pattern of variation in wood density across the ring. In the ring from which the data illustrated in Fig. 3 were obtained, the mean number of files between rays was 4.18, that is to say, nearly half of the tracheid files were contiguous to rays. Thus in about half the files the pattern of change in wall thickness followed the course indicated by the solid line in Fig. 3, while wall thickness in the remaining files followed the course indicated by the broken line. The presence of ray thickenings must therefore greatly widen the range of variation in cross-sectional

cell dimensions, and it may be that accuracy would be gained in comparative work on transverse sections if a distinction were drawn between tracheids in ray files and those in other files.

Finally, it can be suggested that, as the secondary tracheid wall is apparently laid down at the ray crossings at a rate different from elsewhere, a closer investigation of the thickenings might throw further light on secondary growth processes in the tree, while from a practical standpoint it is possible that the thickenings may not only influence the density of wood, as discussed above, but may be of some significance in the behaviour of softwood fibres in papermaking. On disintegration of the cooked chips such fibres tend to bend at points of structural discontinuity that appear to be associated with ray crossings<sup>11-13</sup>. It may be that these discontinuities consist, at least in part, of the ray thickenings that have been the subject of this paper.

Fig. 3. Mean thickness of the tangential tracheid wall and ring width in a single ring of red pine: a comparison between the course of variation in "ray file" (—) as opposed to "control file" (---) tracheids.

I thank the Ontario Department of Lands and Forests and Dr. R. W. Kennedy of the Faculty of Forestry, University of Toronto, for supplying material, and Mrs. W. M. Dillon for the preparation of microscope sections. The work was partly supported by funds from the Department of Economics and Development of the Province of Ontario.

# Infra-red Spectra of Diamond Coat

by

R. M. CHRENKO

R. S. McDONALD

K. A. DARROW

General Electric Research and Development  
Center, Schenectady, New York

Natural diamonds are usually considered as having been grown in magma, the constituents of which are not easily determinable. An infra-red examination of a coated natural diamond indicates the presence of varying amounts of carbonate and water in the concentric rings of the coat region, which suggests that the diamond grew in a magma containing carbonate and water.

THIS article reports infra-red spectra of diamond coat which reveal differences in chemical composition between diamond and diamond coat. Diamond coat is the name given to the concentric layer structure that occasionally surrounds a central core of diamond. This type of diamond is especially prevalent in Congo stones and the coated diamond examined by us was a Congo.

Kamiya and Lang have reported that "the material of the diamond coat is also diamond, but is filled with dust-like matter, individual particles of which are generally of sub-micron size and are not clearly resolvable in the optical microscope". Custers<sup>2</sup> suggests that the foreign matter may be carbon. Seal<sup>3</sup> has examined one sample of diamond coat by electron microprobe and reports that most inclusions contain silicon and oxygen, although he found one inclusion which contained potassium and calcium. We believe we have identified the chief components of the foreign particles\* present in a coated diamond.

We measured the infra-red spectra of a number of areas of a 1.2 mm thick section of a typical coated diamond, using a Perkin-Elmer model 521 infra-red spectrophotometer with a 6-1 beam condenser.

A photomicrograph of this diamond section is shown in Fig. 1. Visual observation and infra-red spectra of this diamond indicate three distinct types of regions. Representative parts of these three regions are labelled on Fig. 1 and correspond to the spectra shown in Fig. 2. These regions are: *a*, the clear centre core; *b*, the clear, yellowish cracked area surrounding the core; and *c*, the region of the rings.

Fig. 2*a* shows the spectrum of the clear centre core of the diamond. This is typical of Type I diamond with strong impurity absorption from 1,000–1,400  $\text{cm}^{-1}$ †.

Fig. 2*b* shows a spectrum of a clear region between the core and the "rings" of the diamond coat. The spectrum differs from that of the core in that the usual 1,370  $\text{cm}^{-1}$  band is absent, and sharp bands are present at 3,107  $\text{cm}^{-1}$  and 1,405  $\text{cm}^{-1}$ . Thus the spectra indicate that the content of impurities in this region is different from that in the central diamond core.

Fig. 2*c* shows a spectrum of a region within the ring structure of the diamond coat. This spectrum differs from that of the core in that the 1,370  $\text{cm}^{-1}$  band is again absent and additional broad bands are present at 3,400, 1,640 and 1,430  $\text{cm}^{-1}$ . Narrower bands are also present at 1,000, 880 and 835  $\text{cm}^{-1}$ . The intensity of these bands in other selected narrow areas is greater in the darker regions

of the coat. The relative intensities of all six bands appear to remain constant throughout the diamond coat. The 3,107  $\text{cm}^{-1}$  band appears only weakly in the spectrum of the diamond coat; and the 1,405  $\text{cm}^{-1}$  band does not appear at all.

The intensity of the very sharp 3,107  $\text{cm}^{-1}$  and 1,405  $\text{cm}^{-1}$  bands may not be represented properly in Fig. 2*c*, however, because of the limited overall transmission of the diamond coat.

Angrist and Smith<sup>5</sup> have reported the absence of the 1,370  $\text{cm}^{-1}$  band in their spectra of diamond coat, as well as the presence of the 1,000  $\text{cm}^{-1}$  band. One of their spectra also shows the 880  $\text{cm}^{-1}$  and 835  $\text{cm}^{-1}$  bands, but they make no specific comment concerning them.

The spectrum of Fig. 2*c* (within the diamond coat) should be compared with the spectra (Fig. 3*a-c*) which are of sodium carbonate, sodium nitrate and hydrated ferric nitrate, respectively. It appears that the broad coat band at 1,430  $\text{cm}^{-1}$  and the narrow 880  $\text{cm}^{-1}$  band are due to carbonate impurity and the broad bands at 3,400  $\text{cm}^{-1}$  and 1,640  $\text{cm}^{-1}$  are due to water, probably water of hydration.

The ratio of the intensities of the 1,430  $\text{cm}^{-1}$  and 880  $\text{cm}^{-1}$  bands in the coat agrees within a factor of two with the ratio in sodium carbonate. The same agreement is found for the 3,400  $\text{cm}^{-1}$  and 1,640  $\text{cm}^{-1}$  bands of hydrated ferric nitrate and coat. These band intensity ratios can vary somewhat for various compounds, but the agreement shown here tends to support our assignment for these four absorption bands.

Fig. 1. Photomicrograph of a Congo coated diamond. The polished surface is a  $\langle 110 \rangle$  plane. ( $\times 30$ .)

\* The distribution of these particles causes the opacity of the rings in the diamond coat.

† Natural diamonds have been classified as Type I or Type II on the basis of their spectra. In the 2.5–50  $\mu$  (4,000–200  $\text{cm}^{-1}$ ) region of the spectrum, all diamonds have weak two phonon (1,900–2,600  $\text{cm}^{-1}$ ) and three phonon (2,800–4,000  $\text{cm}^{-1}$ ) absorption bands characteristic of the diamond lattice itself. Type II diamonds have no other absorptions for wavenumbers less than 1,600  $\text{cm}^{-1}$ , whereas Type I diamonds have additional absorption in the 1,000–1,400  $\text{cm}^{-1}$  and 480  $\text{cm}^{-1}$  regions caused by impurities. Actually the spectra of many diamonds fall intermediate between the defined types and one finds a nearly continuous gradation between types and further subdivisions such as Type 1*a*, 1*b*, 1*IIa*, and 1*IIb*.

We do not attempt to define the specific species responsible for the carbonate and water absorption bands except to say that they are probably present as a separate phase or phases and not as isolated ionic or molecular species in the diamond lattice. The bands are broad, unlike those of most isolated impurities. We believe it is this second phase that gives rise to the light scattering properties of the coat.

We also tried to identify the cation in the coat using an X-ray microprobe, but no metal impurities were detected. Using published data on calcium carbonate<sup>6</sup> in conjunction with our measured infra-red intensities, we estimate the concentration of carbonate ions at approximately  $10^{-18}$ /c.c., a factor of 10–100 below the limiting sensitivity of the X-ray microprobe.

We assign the sharp bands at 3,107 and 1,405  $\text{cm}^{-1}$  seen in Fig. 2b to carbon-hydrogen vibrations in the diamond.

An indistinct band at 1,360  $\text{cm}^{-1}$  and a definite sharper band at 835  $\text{cm}^{-1}$  have the same frequencies as the characteristic bands of nitrates, but such an assignment is very tentative.

It is interesting to relate the appearance of the diamond in Fig. 1 and its carbonate and water content to the possible environment in which this diamond grew. The clear centre core showing a typical Type I absorption spectrum indicates that "normal" conditions of growth existed at the time the core crystallized out of the magma.

At the boundary between the core (Fig. 1, region a) and the intermediate region (Fig. 1, region b) growth conditions evidently changed. Carbonates and water were probably present in the magma but were not incorporated into the inner regions because of the temperatures, pressures, and concentrations.

After the growth of the inner regions, the conditions for carbonate and water inclusion became more favourable and these environmental impurities could crystallize or be trapped in the growing diamond. It is possible that the concentration of these impurities in the melt increased at the boundary between the growing crystal and the melt

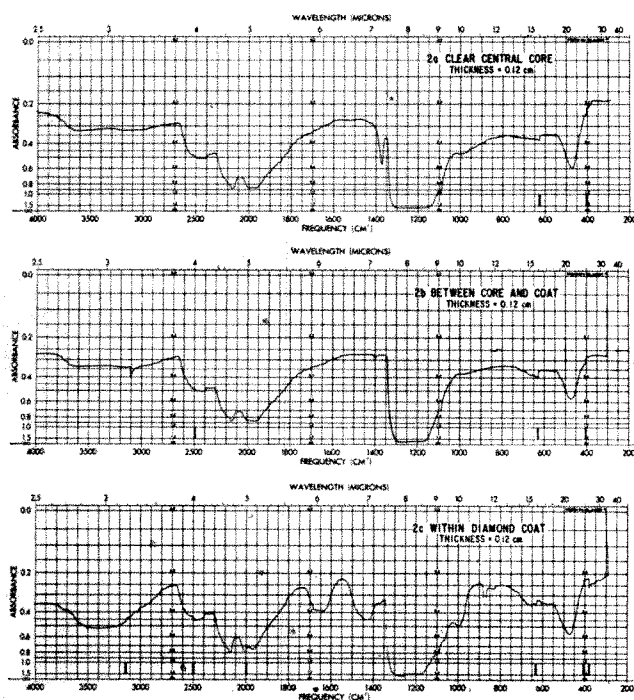

Fig. 2. Infra-red spectra of three areas of the coated diamond of Fig. 1. Thickness of 0.12 cm. Heavy dark vertical lines indicate positions of spectral features that are due to instrumental anomalies.

Fig. 3. Infra-red spectra of sodium carbonate, sodium nitrate, and hydrated ferric nitrate. The spectra were taken as Nujol mulls between salt plates. Heavy dark vertical lines indicate positions of spectral features that are due to instrumental anomalies. The only significant Nujol bands in the spectra are labelled by "N".

until nucleation of the other phases occurred. If this is the mechanism by which the coat was formed, it seems likely that this diamond grew from a phase rich in carbon rather than from a dilute solution of carbon in magma. The formation of rings may be due to alternate supersaturation and depletion of the melt in contact with the surface of the growing diamond. The possibility that the rings were caused by repeated changes of temperature and pressure cannot, however, be ruled out. It should be emphasized that the growth of the diamond itself continued while the impurities were being incorporated. The result gave rise to the "growth rings" as well as the varying amounts of impurities as seen by infra-red spectroscopy.

It is perhaps worth mentioning that the chemical groups responsible for the carbonate, hydrate, and CH bands contain elements that require the presence of only water and a metallic ion, together with diamond itself.

We believe that presence of the other phases during the growth of the diamond caused the formation of the finger-like structures in the coat found by Kamiya and Lang<sup>1</sup>. We cannot imagine how this finger-like structure could have been produced by precipitation of impurities which diffused in from outside an originally clear diamond after its growth. Furthermore, it is even more unlikely that a metal ion and water could both have diffused into the diamond to cause the hydrate and carbonate absorption bands of constant relative intensity throughout the coat.

Several theories have been put forward as to the constituents of the magma during diamond crystallization. Williams<sup>7</sup> gives many analyses of the kimberlite blue ground from which diamond is mined and finds calcium carbonate extremely common, and the carbonate content is very high for some analyses. He favours the secondary origin of the carbonate but says, "... on the other hand, some evidence has been such to tempt me to suggest primary origin for some of it". Rozhkov and Abrashov<sup>8</sup> in a study of kimberlite, have reported the presence of a carbonaceous crust surrounding a number of their diamonds. Our identification of carbonate impurities as

submicron precipitates in the diamond indicates that carbonates were indeed probably present in the magma out of which this diamond grew.

## Eclipse Cycles and Eclipses at Stonehenge

by

R. COLTON

R. L. MARTIN

Department of Inorganic Chemistry,  
 University of Melbourne,  
 Parkville N.2, Victoria

Was Stonehenge used to predict eclipses? Previous claims have assumed a high degree of sophistication on the part of the builders of Stonehenge, and that the number of Aubrey holes (56) is particularly significant. It may be that neither assumption is justified or necessary, and that if the builders of Stonehenge did predict eclipses, they did it in much simpler ways.

RECENTLY, Professor G. S. Hawkins has elaborated the suggestions of Stukeley<sup>1</sup>, Lockyer<sup>2</sup> and Newham<sup>3</sup> that alignments derivable at the ancient monument of Stonehenge have astronomical significance. He has proposed that many additional alignments between various stones and stone holes (mainly Stonehenge 1) and between the trilithons and certain sarsen arches (Stonehenge 111) were deliberately orientated to seasonal extremes of the rising and setting of the Sun and Moon<sup>4</sup>. Subsequently, he has suggested that Stonehenge can be used as a digital computing machine for predicting eclipses<sup>5</sup>. These ideas have since been popularized both in article<sup>6</sup> and book<sup>7</sup> form, and have aroused considerable interest and controversy. In particular, Professor R. J. C. Atkinson, the noted authority on Stonehenge, has been severely critical of the accuracy of Hawkins's alignments and of certain aspects of his archaeological interpretation<sup>8,9</sup>.

Hawkins's theory of the use of the 56 Aubrey holes to predict eclipses is based on the conjecture of a sustained 56 year eclipse cycle containing lunar periodicities which come "in a jumble of 19's and 18's, averaging two 19's to one 18 . . .". It is explicitly stated that the 19 year Metonic cycle<sup>10</sup> is a hitherto unrecognized eclipse cycle, overlooked previously "probably because it runs for only 57 years or so".

In fact, the Metonic cycle is related to phases of the Moon and arises because 235 lunations each of 29.53 days equal 6939.7 days, and 19 tropical years each of 365.2422 days equal 6939.6 days. After 19 years the phases of the Moon are repeated on the same calendar date; however, there is no relationship between the Metonic cycle and eclipses except for the accidental circumstances which will be described later.

Finally<sup>6</sup>, Hawkins reduced his theory algebraically to the commensurability of the eclipse year (synodic revolution of the lunar nodes) and the tropical year; that is, integers  $a$  and  $b$  were sought which came close to satisfying the equation

$$346.620 a = 365.2422 b$$

Certain of the resulting cycles, namely, those of 19, 37, 56, 74 and 93 years, were claimed to have special significance for eclipse prediction, because eclipses should repeat on the same calendar date for many periods before the Moon eventually moves outside the eclipse limits.

While we would agree with Hawkins that the foregoing expression ensures that the Sun, Earth and the lunar nodes are collinear, the fundamental requirement that the geocentric longitudes of the Sun and the Moon differ

by 180° appears to have been overlooked. In other words, none of Hawkins's cycles is an integral number of lunations, so the Moon is not at opposition after successive periods in these cycles. The present article is concerned with exploring the consequences of this unfortunate oversight.

In order to discuss actual rather than computed eclipses<sup>5</sup>, we have referred to the Nautical Almanacs to ascertain the calendar dates of lunar eclipses which occurred between 1855 and 1958 and the data are presented graphically in Fig. 1. It should be noted that since the elements of the Moon's orbit have not changed appreciably since 1500 B.C. the general pattern of eclipses at the time of Stonehenge is also represented by Fig. 1, although only about two-thirds of these eclipses would have been visible at Stonehenge. The exact computation of lunar eclipses is well known to astronomers, but we suspect that the broader comparative analysis of their periodicities presented here may have been overlooked in the past. Certainly, we have been unable to locate any graphical ephemeris similar to Fig. 1. These empirical relationships, however, are particularly relevant when discussing the astronomical attainments of ancient civilizations.

A number of fundamental features of lunar eclipses are at once apparent from Fig. 1. (1) Eclipses most frequently appear in groups of three, and each member of the triplet is separated by twelve lunations (354 days). Occasionally doublets occur, and very rarely quartets are observed. (2) There are usually two lunar eclipses each year, separated by six lunations. (3) Many genuine eclipse cycles can be immediately discerned—some of which are marked by bold lines. (4) A vertical line represents a cycle which gives eclipses on the same calendar date. It is conspicuous that such eclipses repeat every 65 years (in periods of 19, 19 and 27 years) and not every 56 years (19, 19 and 18 years) as claimed by Hawkins.

The important variables which determine the occurrence of eclipses are the relative positions of the Sun, Moon, Earth and the nodes of the lunar orbit. Since the nodes regress in a period of 18.61 years, a synodic revolution of the nodes takes rather less than a tropical year; in fact, it takes 346.62 days. The best known eclipse cycle is the Saros, which some authorities believe was known to the Chaldeans<sup>11</sup>. A Saros period is 18 yr 11 days (18 yr 10 days if five leap years intervene) and it arises because 223 lunations (6,585.32 days) and 19 synodic revolutions of the nodes (6,585.78 days) are nearly identical.

The Metonic cycle used by Hawkins is 1 Saros + 12 lunations (18 yr 11 days + 354 days = 19 yr). In Fig. 2 imagine a lunar eclipse predicted by a Saros cycle occurs with the Earth at position A, and the Moon at opposition exactly at its node. During the following 12 lunations the Earth will proceed to position B, but since 12 lunations are not equal to the period of rotation of the nodes, the nodes are no longer collinear with the Earth-Sun line. The question is, will an eclipse occur?

The mean daily relative motion of the Sun and the Moon's node is  $62' 19''$ , from which it follows that the Sun and the nodes separate by  $368^\circ$  in 12 lunations. There is therefore a difference of  $8^\circ$  between the Earth-Sun line and the nodes compared with the first eclipse. Similar considerations apply to the situation 12 lunations before the Saros eclipse. The condition for a lunar eclipse to occur with certainty is for the full Moon to lie within  $9^\circ$  of its node, but there is the possibility of an eclipse if the Moon is up to  $12.5^\circ$  from its node<sup>11</sup>. It follows that two or three (in exceptional cases four) eclipses can occur with a 12 lunation period between them; after this time the Moon has moved outside the eclipse limits (see Fig. 1). The same result is obtained if the initial eclipse were placed just inside the eclipse limits. Since the 19 year period differs from a quite accurate eclipse cycle by 12 lunations, it is clear that the number of eclipses that can occur in a cycle with this period is similarly limited.

Of the many eclipse cycles that can be seen in Fig. 1, only a limited number survive for more than a few periods. This is caused by poor commensurability in the expression

$$29.53059x = 346.62y/2$$

where  $x$  and  $y$  are integers. It is a simple matter to find integral values of  $x$  that give almost integral values of  $y$ .

Fig. 1. Lunar eclipses (1855-1958). Key to diagram: each circle represents a lunar eclipse on the day of the month indicated. When an eclipse spans two calendar dates the earlier one is noted. The following illustrative eclipse cycles are marked by full lines (see text). A—135 lunations; B—804 lunations; C—223 lunations; D—311 lunations; E—88 lunations; F—41 lunations.

The incommensurability between lunations and synodic revolutions can be used with the eclipse limits to determine the number of periods for each cycle. The results are summarized in Table 1 for values of  $x$  up to 1,000. All cycles which survive for less than 10 periods have been eliminated (except the very important 41 lunation period). The convention used is to express errors as positive if the lunations are longer than the synodic revolutions of the nodes.

Fig. 2.

A remarkable feature that emerges is that all the eclipse cycles consist of the addition of small integral multiples of the two shortest cycles; for example, the Saros (223 lunations) is  $(3 \times 47) + (2 \times 41)$  lunations. The incommensurability of the 41 and 47 lunation periods are in the opposite sense and all other cycles are merely linear combinations of multiples of these cycles in which the additive error tends to zero (Table 1). Algebraically the cycles conform to the expression  $(41m + 47n)$ , where  $m$  and  $n$  are the integers,  $m = 0, 1, 2, \dots$  and  $m \leq n \leq 2m$ . The 358 lunation cycle is especially noteworthy as it survives between 12,000 and 17,000 years.

It emerges that some of the cycles listed in Table 1 were those used by ancient civilizations to predict eclipses, but it will be clear that the longer the period the less likely it would be for ancient peoples to discern a particular cycle. We have marked a few eclipse cycles in Fig. 1; the Saros (line C) is notable because each eclipse occurs close to the calendar date of the previous one. It may well be that this cycle was detected by early civilizations because its period is close to that of both the Metonic cycle and the regression of the nodes.

Line A (135 lunations) is the cycle used by the ancient Chinese as an eclipse predictor<sup>12</sup>. They were well aware of the Metonic cycle which they called the *chang*, and they also used a period four *changs* (76 years) called the *pu*. Their numerology was notable in that they recognized 81 lunations as an integral number of days, which when combined with the 135 lunation period gave a cycle of 405 lunations ( $m = 3, n = 6$ ) which is both an eclipse cycle and an integral number of days<sup>12</sup>.

In view of Professor Hawkins's attempts to find an eclipse cycle which gives eclipses on the same calendar date the 804 lunation cycle (line B) is of some interest. The repeating unit of 65 yr 2 days is made up of two 19 yr intervals and one of 27 yr 2 days. This is a true eclipse cycle because the incommensurability in the two 19 yr periods (that is,  $-16''$ ) is almost balanced by an error of

Table 1. ECLIPSE CYCLES

Lunations	Days	Syn. revs.	Days	Error (days)	Error (°)	No. of periods

\* Three unevenly spaced eclipses per period—see text.

+15.09° in the 27 yr 2 day period (334 lunations), so after the full period the relative movement of the nodes and the Earth-Sun line is only 0.91° and the cycle can repeat many times.

Also marked on Fig. 1 (dashed lines) are the manoeuvres necessary to obtain the 19, 19, 18 year sequence as described by Hawkins, although it is actually 19, 19, 18 years 11 days. It is inherently a very short cycle because there is no way to compensate for the error in the two 19 year periods. If it were not for the fact that his Stonehenge computer theory demands a 56 year cycle, a far more logical move would be to follow the 47 year sequence 19, 19 and (9 years minus 9 days), which gives the very good 581 lunation cycle (dashed line, Fig. 1). The error in the two 19 year periods is balanced almost exactly by that of the (9 year minus 9 day) period. Obviously the 804 and 581 lunation cycles are far superior in fulfilling the conditions sought by Hawkins.

Certain occasional irregularities in the 804 lunation cycle serve to underline the occupational hazards of making priestly predictions of lunar eclipses. Thus, the intervention of random groupings of eclipse doublets or quartets can increase or decrease the anticipated interval between eclipses on a particular cycle. For example, the quartet between 1908 and 1911 resulted in an extra eclipse on November 6, 1911, giving intervals of 19 and 8 years, rather than 27 years. Similarly, the more frequently occurring eclipse doublets caused eclipse omissions near May 24, 1937, June 1, 1882, and December 18, 1926, which resulted in 46 year periods (19+27) between eclipses. Prophecies in mid-October would have been particularly disastrous since successive eclipses expected on October 16, 1921, and October 18, 1948, did not occur, so that an interval of at least 65 years is involved.

It would seem safe to assume from the discussion so far that the Aubrey holes at Stonehenge were not constructed to predict eclipses on a 56 year cycle. Recently<sup>13</sup>, Professor Hoyle has suggested a most elegant and ingenious alternative way of using the Aubrey holes to predict eclipses, but the success of his method is not confined to circles of 56 holes. Hoyle regards the Aubrey circle as the ecliptic on which stones representing the Sun, Moon and the two lunar nodes are moved in such a way as to give approximately their periods of rotation. These periods are compared in Table 2 with corresponding values for other hypothetical circles, from which it is seen that 56 is not a unique number for this type of predictor. Viewed in the context of the limited astronomical knowledge of the Stonehenge society, the method appears to be an unlikely one because it is very sophisticated and in the calibration procedure, particularly, requires that the Stonehenge people were capable of storing rather subtle information for several periods of 18.61 years. Moreover, the method predicts every lunar and solar eclipse, but it can give no information as to which of these would be visible at Stonehenge; in fact, exclusion of an eclipse would be its only safe prediction.

Finally, we would like to propose a very simple method of predicting only those lunar eclipses visible at Stonehenge. It has been known from the third millennium B.C.

Table 2. NUMEROLOGICAL ECLIPSE PREDICTORS

No. of holes	Sun (period 365.25 d)		Nodes (period 18.61 yr)		Moon (period 29.53 d)*	
	Method	Period obtained	Method	Period obtained	Method	Period obtained
18	1 hole/20 day	360	1 hole/yr	18	3 holes/5 day	30
19†	1 hole/19 day	361	1 hole/yr	19	2 holes/3 day	28.5
36	1 hole/10 day	360	2 holes/yr	18	5 holes/4 day	28.8
37†	1 hole/10 day	370	2 holes/yr	18.5	5 holes/4 day	29.6
56	2 holes/13 day	364	3 holes/yr	18.67	2 holes/day	28.0
74	1 hole/5 day	370	4 holes/yr	18.5	5 holes/2 day	29.6

\* Since the Moon marker is adjusted opposite to, or coincident with, the Sun at each full Moon and new Moon respectively as seen from the Earth, the period required is the lunar month of 29.53 day, not the sidereal revolution of Moon (27.32 day) as Hoyle states.

† Obvious practical difficulties arise with odd numbers of holes since the Sun and Moon cannot be exactly opposite each other.

that for a lunar eclipse to occur the Sun and the full Moon must be diametrically opposed in the sky. If, in addition, the Moon rises a short time (up to 15–30 min, depending on the declination of the Moon) before the Sun sets, an eclipse of the Moon will occur that night and will be visible. If the time interval is longer, the eclipse will not be seen; if the full Moon rises after the Sun has set, the eclipse is already past, as Hawkins has mentioned. The even spacing of the Aubrey holes on an accurate circle<sup>14</sup> would enable it to serve as a giant protractor used by the observer standing at its centre to judge whether the setting Sun and rising full Moon were exactly opposite each other in azimuth. We believe that with practice such predictions could be made with considerable accuracy; the observer would be warned of the possibility of a forthcoming eclipse by noting how previous full Moons came progressively closer to a position in line with the Sun.

If this method of eclipse prediction were used, it could provide the reason for the construction of the many stone circles found in the British Isles for which no completely convincing purpose has been proposed. The advantage of the method is its simplicity, but it has the disadvantage that it is poor for predicting solar eclipses because of the difficulty of observing the Moon near conjunction. Since solar eclipses are rare events at any given spot, however, this is probably not a serious objection. It is clear that this type of predictor would work with any reasonably large number of holes, and we suspect that there are 56 Aubrey holes for quite different reasons, which will be discussed in a later communication.

We thank Dr. C. G. Barraclough, of the Department of Physical Chemistry, for his helpful comments.

## LETTERS TO THE EDITOR

## ASTRONOMY

## Helium in the Galactic Disk B Stars

Greenstein and Münch<sup>1</sup>, and Sargent and Searle<sup>2</sup>, have recently shown that the atmospheric helium abundance in the halo and globular cluster B stars is low compared with that for normal B stars in the Galaxy. Greenstein, Truran and Cameron<sup>3</sup> have suggested that the low abundance may be the result of gravitational diffusion of helium from the atmosphere to a lower layer within the star. They consider that normally mixing currents set up by stellar rotation would counteract such diffusion. In contrast to galactic disk B stars, most of the halo stars appear to be slow rotators. This result is apparently confirmed by Sargent and Strittmatter<sup>4</sup>, who have discussed the weak helium line stars in Orion and conclude that they are intrinsically slow rotators, and that the anomaly is an atmospheric one.

In this communication we would like to report related results on 425 field B stars which suggest that the apparent helium abundance depends on the rotational velocity. The observational data are taken from Walker and Hodge<sup>5</sup>.

There is a significant positive correlation for spectral types B2 to B5 between the equivalent widths of the He I lines at wavelengths of 4388 and 4471 Å, and the values of the projected rotational velocity  $v \sin i$ , based on the half widths of the two He I lines. The correlation between the equivalent widths of H $\gamma$ , a measure of surface gravity, and  $v \sin i$  is always much smaller than that between the He I lines and  $v \sin i$  and not always of the same sign. The relevant correlation coefficients between the logs of the observed quantities are given in Table 1.  $W$  refers to equivalent width and the subscripts identify the line. For the He I lines we use the correlation between  $\log W_{4471}$  and  $\log (v \sin i)_{4388}$  to eliminate any effects of errors of measurement in  $W$  and  $v \sin i$  for the same line. The number of stars in each group is given by  $n$ . An example of the correlation for B4 stars is shown in Fig. 1.

After examination of the reduction procedure, we have concluded that systematic errors in estimating the level of the continuum or the line profile are not responsible

Fig. 1. The relation between the equivalent width  $W$  of the He I line at 4471 Å and the half-width  $H$  of the He I line at 4388 Å for B4 stars, showing the effect of rotational velocity, which determines  $H$ , on the strength of the He I lines.

Table 1. CORRELATION COEFFICIENTS FOR SPECTRAL TYPES B0 TO B5

Spectral type	$(W_{4471}, v \sin i)$ $r^*$	$(W_{H\gamma}, v \sin i)$ $r^*$	$n$
09, B0	0.05	0.12	46
B1	0.01	0.00	69
B2	0.26	-0.04	66
B3	0.32	-0.15	130
B3e	0.63	-0.36	23
B4	0.60	0.24	48
B5	0.29	0.02	66

$r^*$ , Correlation coefficient between the logs of the quantities in parentheses.

for the correlation between  $\log W_{4471}$  and  $\log (v \sin i)_{4388}$ . There is clearly a considerable scatter, since none of the correlation coefficients is very high. The distribution of points at all spectral types is, in fact, triangular (see Fig. 1), an effect which can be understood if the helium line intensities are sensitive to rotational velocity  $v$  but insensitive to  $\sin i$ . According to Greenstein and Münch<sup>1</sup>, the effects of changes in temperature and pressure over the surface caused by the rotation are expected to be small, and this is confirmed by our observation that the variation of the equivalent widths from type to type is less than the scatter within each type. We could improve the correlations considerably in the range 09 to B2 and at B5 by rejecting five very deviant points, but we prefer not to do this, since there is no other evidence that these stars are peculiar. These are, however, the only stars out of 425 which show low  $W_{4471}$  and high  $v \sin i$ .

The B3e stars were analysed as a separate group since the emission line stars have been thought to be rapidly rotating, and the observed variation of the equivalent widths of the He I lines with  $v \sin i$  would then reflect largely a variation with  $\sin i$  not  $v$ .

The frequency of B3e stars with low  $v \sin i$ , however, appears to be incompatible with a uniformly high  $v$  and a random distribution of  $i$ . Some of our B3e stars must therefore be intrinsically slow rotators. A similar conclusion is reached by Schild<sup>6</sup> in a study of the Be stars in  $\delta$  and  $\gamma$  Persei. The Be stars, therefore, give us no information about  $\sin i$  effects. The behaviour of the helium lines in B3e stars is, in fact, observed to parallel that of the normal B3 stars. Sharp line B3 and B3e stars have similar He I lines (Sargent and Searle<sup>7</sup>), but this cannot be used as evidence for the absence of  $\sin i$  effects. Other arguments such as those made previously must be used. Visual inspection of the original plates shows that other He I lines behave in the same way as those at 4471 and 4388 Å.

These results are qualitatively compatible with any mechanism for removing helium from the atmospheres of slowly rotating stars, such as that of Greenstein, Truran and Cameron, and consistent with the arguments of Sargent and Strittmatter that the abundance anomalies cannot extend far into the interior of the stars. Caution must therefore be exercised in comparing the helium content of the atmospheres of certain stars with the implications of some cosmologies concerning primordial helium abundance. A more detailed account of this research will appear elsewhere.

We thank Dr. N. Woolf for helpful discussions, and the U.S. Office of Naval Research for partial support.

## Detection of $\beta$ -Transitions in the Recombination Spectrum of Hydrogen near 9 cm Wavelength

THE detection in galactic emission nebulae of several of the hydrogen lines corresponding to transitions between levels with large principal quantum numbers has already been reported<sup>1-4</sup>. The lines were in the frequency range 8,873–1,424 Mc/s, corresponding to transitions in the range  $90\alpha$ – $166\alpha$ , using the notation suggested by Palmer and Zuckerman<sup>4</sup> in which  $n\alpha$  indicates a transition from level of quantum number  $(n+1)$  to  $n$ . A transition from  $(n+2)$  to  $n$  is indicated by  $n\beta$  (see Fig. 1a).

In predicting that hydrogen recombination lines should be detectable, Kardashev<sup>5</sup> calculated that  $\beta$ -transitions would be considerably weaker than  $\alpha$ -transitions, which are themselves weak. In recent observations of the intense HII regions, Orion-A and M17,  $126\alpha$  intensities of several degrees were recorded with the Parkes radio telescope. An attempt was therefore made to detect  $\beta$ -lines at nearby frequencies.

Two lines,  $158\beta$  and  $159\beta$ , were observed in the nebulae at frequencies near the calculated rest frequencies of 3,272.219 and 3,211.245 Mc/s, respectively; in the calculation the Rydberg constant  $R$  was taken as  $3.2880559 \times 10^{15}$  sec<sup>-1</sup>. The rest frequency of the  $126\alpha$  line was 3,248.713 Mc/s.

The half-intensity beamwidth of the 210 ft. telescope was 6 min of arc at about 3,250 Mc/s. The receiver consisted of a double side band mixer in front of a 48-channel recording system, with filters 37 kc/s wide spaced 33 kc/s apart. The overall system noise temperature with the telescope pointing at either Orion or M17 was 480° K, and when pointing at cold sky 300° K. The local oscillator was switched by 2.16 Mc/s from "signal" to "reference" frequencies. The first intermediate frequency was 30.43 Mc/s. Under these conditions, the  $158\beta$  line appeared in the signal band but, in addition, the  $159\beta$  line, 60.974 Mc/s lower in frequency, appeared in the image reference band as a negative deflexion.

The observational procedure was to record four or six profiles on source and the same number at a reference point  $\pm 12$  min away in right ascension. A single forty-eight point profile was recorded in 2 min of time. The

Fig. 1. a, The energy levels involved in the  $\alpha$  ( $\Delta n=1$ ) and  $\beta$  ( $\Delta n=2$ ) transitions. b, The observed profile for the combination of the  $158\beta$  (positive) and  $159\beta$  (negative) emissions in Orion A. The baseline is dashed. The expected pattern shown below was derived from the  $126\alpha$  line reduced by a factor of 0.2. The upper radial velocity scale refers to the  $158\beta$  line, the lower to the  $159\beta$  line. The ordinate is intensity.

Fig. 2. The observed profiles for the combinations of the  $158\beta$  and  $159\beta$  emissions in M17. The expected patterns shown below were derived from the  $126\alpha$  line reduced by a factor of 0.16. The change of pattern from a to b was caused by retuning the receiver. The ordinate is intensity.

sequence of observations was such that changes in baseline as a result of changes in the zenith angle of the telescope and linear drifts with time were eliminated. Thirty-six sets of profiles were taken on each source. The intensity scales for the "on-source" and "reference-point" observations were different because of the different system temperature (see above). The scales were measured and corrections applied in the computer reductions.

The average spectrum as observed at intermediate frequency is shown in Fig. 1(b) for Orion A. For convenience, corresponding radial velocity scales (referred to the local standard of rest (LSR)), which are different for the two lines, are included: the upper for the  $158\beta$  and the lower for the  $159\beta$  transitions. The observed profile can be compared with the expected profile, which was obtained from the  $126\alpha$  observations<sup>4</sup> by suitably adjusting the frequency (that is, velocity) scales and by reducing the amplitude to be comparable with the  $\beta$ -amplitude. Now the radial velocities at points of zero intensity A, B and C are well established. The baseline between these points, however, is somewhat uncertain. The first approximation assumed straight lines from A to B and B to C. This proved sufficient in Fig. 1b, because such a baseline closely approximated one obtained from an observation of a point on the Crab Nebula (no hydrogen lines present) of continuum aerial temperature equivalent to that of Orion A.

Two profile patterns are shown for M17 in Fig. 2. The insertion of linear baselines is not realistic in these cases and suitably curved baselines are suggested following the obvious trends from observations outside the lines. But the validity of the line emission was demonstrated when a suitable change in local oscillator frequencies caused the sense of the S-shaped pattern to reverse from Fig. 2a to Fig. 2b. In making measurements from these profiles both the linear and the estimated baselines have been included, appropriately weighted and errors accordingly allotted.

Table 1 contains estimates of the central line intensity in terms of aerial temperature,  $T_{L\beta}$ , the ratio of the central line intensity to the continuum temperature  $T_c$ , and the ratio of the intensities of the  $\beta$  and  $\alpha$  transitions,  $I(158\beta)/I(126\alpha)$ , together with the radial velocity for Orion A and M17. The ratios are significantly higher for M17.

Table 1. SUMMARY FOR H-LINES 158 $\beta$ , 159 $\beta$  AT FREQUENCIES 3,272-219, 3,211-245 Mc/s

		Orion A	M17
$T_{1\beta}$	°K	0.8	1.2
$T_{1\beta}/T_e$	%	0.44	0.67
$I(158\beta)/I(126\alpha)$		0.13 ( $\pm 0.03$ )	0.22 ( $\pm 0.04$ )
R.V. (peak)	km/s	-4	+22

The expected intensity ratios of the  $\beta$  and  $\alpha$  transitions can be derived from the fundamental formulae of Menzel and Pekeris<sup>7</sup>. If the principal quantum number of the lower level of the  $\beta$ -transition is written as  $q$  and the corresponding number for the  $\alpha$ -transition as  $p$ , then from equations (1.2) and (1.3) of ref. 7, the ratio of the total emissions for small optical depths in both lines is given by

$$\frac{E_{q+2,q}}{E_{p+1,p}} = \frac{N_q}{N_p} \cdot \frac{f_{q+2,q}}{f_{p+1,p}} \cdot \left[ \frac{\nu_{q+2,q}}{\nu_{p+1,p}} \right]^3 \quad (1)$$

where the  $f$ 's and  $\nu$ 's are the oscillator strengths and frequencies of the transitions shown as subscripts. The populations  $N_p$ ,  $N_q$  of levels  $p$  and  $q$  are given by Boltzmann's formulae if local thermodynamic equilibrium (LTE) applies, that is

$$\frac{N_q}{N_p} = \frac{q^2}{p^2} \cdot e^{-(h\nu_{q,p}/kT)} \\ = \frac{q^2}{p^2} \text{ as } e^{-(h\nu_{q,p}/kT)} \approx 1 - 0.00035 \text{ for } T = 10^4 \text{ °K.} \quad (2)$$

In equation (1), we may rewrite

$$\frac{f_{q+2,q}}{f_{p+1,p}} = \frac{f_{q+2,q}}{f_{q+2,q+1}} \cdot \frac{f_{q+2,q+1}}{f_{p+1,p}} = \frac{0.113(q+2)}{(p+1)} \quad (3)$$

when the values of  $f_{n,n-1} = 0.18n$  and  $f_{n,n-2}/f_{n,n-1} = 1/8.8$  given by Kardashev<sup>5</sup> are used. Finally, if (2) and (3) are substituted in (1) and if the frequencies of the  $\beta$  and  $\alpha$  transitions are taken as equal (the average  $\beta$ -frequency 3,242 Mc/s is very close to 3,248, the  $\alpha$ -frequency), we obtain

$$\frac{E_\beta}{E_\alpha} \approx \frac{0.113q^2(q+2)}{p^2(p+1)} \quad (4)$$

$$\approx 0.224 \text{ for the } 158\beta/126\alpha \text{ transition} \\ \approx 0.230 \text{ for the } 159\beta/126\alpha \text{ transition.}$$

These numbers will also be the ratio of the central line intensities if the line widths are the same as is the case for Doppler broadening.

Table 1 shows that the observed central intensity ratio for M17 is very close to the value given here, but that for Orion is significantly lower.

Recently, Goldberg<sup>8</sup> has directed attention to a dependence of the  $\alpha$ -line/continuum ratio on the continuum optical depth and to possible differences between the line excitation temperature and the electron temperature,  $T_e$ . The  $\beta/\alpha$  intensity ratio is useful because it is independent of optical depth in the continuum. So, to explain the present observations of Orion A, either there must be a departure from LTE or the broadening must not be solely Doppler. If only the former is important and the ratio of the population of level  $n$  to that in LTE is denoted by the usual symbol  $b_n$  ( $b_n = 1$  for LTE) then the ratio of  $\beta/\alpha$  intensities to that in LTE is given from Goldberg's equation (4) as

$$\frac{\{I(158\alpha)/I(126\alpha)\}}{\{I(158\alpha)/I(126\alpha)\}_{\text{LTE}}} \\ = \frac{1 - \frac{b_{160}}{b_{158}} \cdot e^{-h\nu_\beta/kT_e}}{1 - \frac{b_{127}}{b_{126}} \cdot e^{-h\nu_\alpha/kT_e}} \quad \text{and} \\ \approx \frac{b_{160} - b_{158}}{b_{127} - b_{126}}$$

under conditions envisaged by Goldberg. The lower  $\beta/\alpha$  ratio for Orion would then imply that the  $b_n$  relation-

ship was flattening off at large  $n$  in a similar way to Seaton's<sup>9</sup> theoretical curve (IV), calculated for  $T_e = 10^4$  °K and an electron density of  $10^4/\text{cm}^3$ .

Our observations<sup>6</sup> of the H126 $\alpha$  line in Orion A have shown, however, that the line width is appreciably greater than might be expected from an extrapolation (proportional to frequency) of the observations<sup>1,2</sup> of the 109 $\alpha$  and the 94 $\alpha$  lines. Thus for Orion A, broadening effects other than Doppler are significant. (The H126 $\alpha$  width in M17 was closely proportional to frequency.) The full amount of the correction for broadening in Orion A is expected to come out of a projected series of measurements of, say, the 158 and 159 $\alpha$  intensities. Such information may shed light on the true population distribution at high quantum numbers.

## PLANETARY SCIENCE

### Transient Lunar Brightening

MIDDLEHURST has examined<sup>1</sup> the relationship between transient lunar brightening and solar activity as measured by the incidence of sunspots (compare ref. 2). Working with a sample of 125 lunar events, she found no correlation between lunar brightening and the mean sunspot number for the month during which such an event occurred. Hence, she suggests that the reported events must be attributed to some physical phenomenon other than luminescent emission induced by enhanced solar wind bombardment or any other direct consequence of solar activity.

Most of the reported events appear to be of short time duration (less than 1 h), and it would seem more appropriate to make such a statistical investigation in terms of a parameter indicating the variation within a time interval much shorter than 1 month. Specifically, an experiment on *Mariner II* by Snyder *et al.*<sup>3</sup> showed that the velocity and energy flux of the solar wind are not strongly correlated with overall sunspot activity as determined by sunspot number and 10.7 cm radio noise emission but are convincingly and positively correlated with the magnitude of the planetary geomagnetic disturbance index  $K_p$ . This index measures the range of the variations in the geomagnetic field intensity within a period of 3 h and is scaled over the range 0- to 9+. The sum over 24 h, designated  $\Sigma K_p$ , is the sum of the eight values of  $K_p$  for a day and thus ranges from 0- to 75-. Internationally determined values of  $K_p$  are available for the past 34 years<sup>4</sup>.

The  $K_p$  index is therefore relevant for indicating the intensity of solar wind bombardment of the Moon. A relation between lunar eclipse brightness and the sunspot cycle, proposed earlier by Danjon<sup>5</sup>, is questionable, in view of my recent study<sup>6,7</sup> on the basis of a number of more reliable results from lunar eclipse photometry. Instead, it has been found that the eclipsed Moon seems to appear brighter when the eclipse occurs on a day of higher  $K_p$ . Thus, it is interesting to investigate the relationship between the occurrence of lunar brightening events and solar wind activity by way of the secondary parameter, the  $K_p$  index.

In a previous paper<sup>7</sup>, I have examined the values of  $K_p$  on the dates of about twenty recorded luminescence observations, but the number of dates included in the analysis does not seem to be sufficient to allow any convincing conclusion. The 3 h values as well as the 24 h sums of  $K_p$  indices are available without interruption since January 1932 (ref. 4).

The most recent catalogue compiled by Middlehurst and Burley<sup>8</sup> lists reports of 238 lunar brightening events, including 122 on known dates since 1932. Since the exact time of the observations is usually not known, the 24 h sums,  $\Sigma K_p$ , are used in the following analysis. A total of 366  $\Sigma K_p$  values are taken, one for the day of each event, one for the preceding day, and one for the following day. The frequency distribution of  $\Sigma K_p$  values on the event days is found by grouping the values into twelve classes, 0- to 5+, 6- to 10+, 11- to 15+, . . . , etc., with the exception that the final class includes all values greater than 55+. A second frequency distribution is found for the indices for the 3 day intervals, including each event day. Finally, a third frequency distribution is found by taking the  $\Sigma K_p$  values for each of the 31 days of every January between 1932 and 1966.

These three frequency distributions are shown in Fig. 1, with the area under each curve normalized to unity. The distribution for event days is shown by the solid line, and the distribution for the 3 day periods including the day before and after each event is shown by the dotted line. The broken line represents the distribution for 1,054 days in January of the past 34 years and is taken to represent the distribution of  $\Sigma K_p$  for a random selection of dates. The degree of fluctuation of the resulting distribution for each case may be compared by noting that the vertical shift of each point due to the difference of one day in each interval is 0.41, 0.14 and 0.05 of the ordinate unit (2 per cent) for the solid, dotted and broken lines, respectively.

I conclude from Fig. 1 that the frequency distribution of  $\Sigma K_p$  indices for days on which lunar brightening has been reported is not significantly different from the distribution for a random selection of days. Thus, in agreement with Middlehurst<sup>1</sup>, it appears that lunar brightening events are not related to solar wind activity.

Fig. 1. The solid, dotted, and broken lines represent, respectively, the frequency distributions of  $\Sigma K_p$  values of the days of lunar brightening events, on the three days near each of the events, and on arbitrarily chosen dates.

An implicit assumption of the foregoing analysis is that lunar luminescence under solar wind bombardment, if indeed of observable intensity, is a prompt effect (compare ref. 9 for a discussion of the possibilities of energy storage and subsequent release at the advancing terminator).

I thank Professor James A. Van Allen for reading the manuscript and offering many valuable comments. This work was supported in part by a grant from the U.S. National Science Foundation.

### Systematic Errors in the Palaeomagnetic Inclination of Sedimentary Rocks?

Van Andel and Hospers's<sup>1</sup> conclusion that an inclination error is present in sedimentary rocks throughout the geological column is considered highly premature for the following reasons. (a) Palaeomagnetic data from varves which have a depositional remanent magnetization (d.r.m.) for which it is suspected<sup>2</sup> there may be an inclination error are grouped with those from sedimentary rock types (for example, red beds) which have crystallization remanent magnetism (c.r.m.) for which an inclination error is most unlikely. (b) Certain pairs of data used by van Andel and Hospers are invalid for the purpose of their analysis, as shown later in this communication. (c) Their statistical method is not satisfactory in that they have to exclude data for which the inclination difference between lavas and sediments  $|I^*| - |I| = 0$ . The method is crude in that no account is taken of the magnitude of the inclination error for each data pair or of its accuracy.

Let us consider some important palaeomagnetic aspects of the data pairs listed by van Andel and Hospers<sup>1</sup> in their Table 1.

**Data pair 1.** The sediments (poles 202 and 203) are Cambrian, but the age of the Aberdeen gabbros (pole 201) ranges between 404 and 498 m.y. (Silurian-Ordovician)<sup>3</sup>. These data are therefore invalid, because they are probably different in age.

**Data pair 8.** The Carboniferous directions in Britain fall into two distinct groups<sup>4</sup>. In Table 1, where they are summarized, they are referred to as CI and CII. Directions CI may correspond to Triassic remagnetization<sup>4</sup>, so that it may not be valid to use entry 8 (a) as a test of the presence of inclination error. Thus entry 8 in van Andel and Hospers's Table 1 should be replaced by entry 8 (b) in my Table 1.

Table 1. SUMMARY OF BRITISH CARBONIFEROUS PALAEOMAGNETIC RESULTS

Entry No.	Direction group	Sedimentary rocks				Igneous rocks				$\Delta D$	$ I^*  -  I $
		N	D	I	a	N	D	I	a		
8 (a)	CI	4	35°	+29°	13°	1	47°	+38°	(10°)	12°	+9°
8 (b)	CII	4	15°	-36°	15°	4	25°	-30°	18°	10°	-6°

**Data pair 12.** The Siberian Triassic igneous poles (820 and 825)<sup>5</sup> differ significantly from each other. When directions  $D^*$  and  $I^*$  are calculated for each of these corresponding to the site of sedimentary formations 821, the sign of  $|I^*| - |I|$  is positive for igneous formation 821,

while this sign is negative for igneous formation 825 (see Table 2). These results contradict each other. Entry 12 in van Andel and Hospers's Table 1 is therefore invalid.

Table 2. PALAEOMAGNETIC RESULTS FOR THE TRIASSIC, SIBERIA

Entry No.	Ref.	Sedimentary data		Ref. No.	Igneous data		$D^*$	$I^*$	$\Delta D$	$ I^*  -  I $
		$D$	$I$		Pole					
12a	821	130°	+68°	820	60° N 133° E	155°	+79°	25°	+11°	
12b	821	130°	+68°	825	34° N 153° E	115°	+63°	15°	-5°	
12	821	130°	+68°	820+825	47° N 146° E	128°	+72°	2°	+4°	

**Data pair 14.** The igneous data (pole 1015) have too small a standard deviation ( $\delta = 4.4^\circ$  computed from precision  $K = 38.9$ )<sup>5</sup> to contain the full secular variation<sup>6</sup> of the Cretaceous geomagnetic field. Thus pole 1015 is most unlikely to be the true Cretaceous palaeomagnetic pole (that is, the Cretaceous pole of rotation) but is rather a non-axial virtual pole corresponding to the mean of a number of Cretaceous geomagnetic poles representing too short an interval of time for non-axial components of the field to have been averaged out. Thus the directions  $D^*I^*$  computed from pole 1015 are not Cretaceous axial dipole field directions and should not have been used by van Andel and Hospers in their analysis.

**Data pair 19.** The n.r.m. of the Akchagyisk and Apsheronsk stages (pole No. 1230) is only partly stable because it exhibits streaking<sup>5</sup>. This was corrected for by rotating the measured mean direction of magnetization along the great circle passing through it and through the present dipole field direction away from the latter. The magnitude of this correction was quite arbitrary and might well have been over-estimated. The effect of making it was to decrease the inclination of the measured mean direction, and the fact that this arbitrarily corrected value,  $I = 40^\circ$ , is less than that computed for the present axial dipole field is entirely meaningless. This pair of data is therefore invalid.

**Data pairs 21, 22 and 23.** In each of these pairs, the sediment is a varved clay the n.r.m. of which is known to be depositional and therefore not typical of the bulk of sediments studied palaeomagnetically.

The remaining palaeomagnetic data, the validity of which have not been contested and which are therefore still available for van Andel and Hospers's sign test, are listed here in Table 3. Of their twenty-three pairs they rejected three (Nos. 2, 3 and 4) because the inclinations  $I^*$  and  $I$  were of opposite sign (marked "/" in right-hand column). They rejected two more (Nos. 10 and 22) because the sign of the inclination error was zero, thus biasing their statistics in favour of their conclusion that an inclination error is present in sedimentary rock magnetic data. Even if following them we exclude these two data pairs, however, we still cannot reach any significant conclusions as indicated in Table 4.

Table 4

Range in declination difference ( $\Delta D$ )	Total No. of pairs (N)	No. of pairs with positive inclination difference (n)	Probability $P^*$ (per cent)	Range of $\alpha$ for which $P^* > 5$ per cent
All sediments included				
$\leq 90$	14	7	60.8	2-12
$\leq 45$	13	7	50	2-11
$\leq 25$	10	7	17.1	1-9
$\leq 5$	3	3	12.5	0-3
Varves excluded				
$\leq 90$	12	5	30.8	2-10
$\leq 45$	11	5	30	1-10
$\leq 25$	8	5	36.3	0-8
$\leq 5$	1	1	50	0-1

\*  $P$  is the probability that of  $N$  pairs of data,  $n$  pairs will have a positive inclination error purely by chance. If the hypothesis of systematic flattening of the palaeomagnetic inclination in sediments were true,  $P$  would be smaller than a few per cent (5 per cent is often accepted in statistical work).

The presence of an inclination error has been shown in laboratory experiments on varved clays<sup>2</sup>; therefore, as a test of whether such an error is present in the n.r.m. of other kinds of sediments, the pairs of data containing results from varved clays should be set aside. This leaves twelve pairs of data (see Table 4).

Another objection to van Andel and Hospers's analysis is that they ignored the magnitude of the inclination difference  $|I^*| - |I|$ . Their method is incapable of taking account of pairs for which this difference equals zero, as already noted. A better approach using the few data presently available is to find the mean value of the inclination difference and its standard deviation. Using all pairs for which  $\Delta D \leq 25^\circ$ , we find that the inclination difference =  $+2.2^\circ \pm 2.2^\circ$ , with  $N = 12$ . This is not significantly different from zero, and data from varved clays for which the presence of an inclination error is physically plausible are included. Excluding the data from varves, the inclination difference is  $+0.9^\circ \pm 2.8^\circ$  ( $N = 9$ ), which is not significantly different from zero.

### Evidence for Palaeomagnetic Inclination Error in Sediment

THE inclination error ( $\delta$ ) in sediment is the difference between the inclination of the ambient field and that of the remanent magnetization acquired by a sediment<sup>1</sup>. The error is reckoned positive (negative) if the inclination of remanence is less (greater) than that of the field. Inclination errors in nature may be studied by comparing observed inclinations in sedimentary rocks ( $I_o$ ) with that expected ( $I_e$ ) from studies of contemporaneous isotropic igneous rocks which are not subject to the error. There are two methods. Results from nearby localities may be compared directly (method 1), or results from widely spaced localities may be compared by calculating the expected inclination ( $I_e$ ) calculated from the palaeomagnetic pole derived from observations of igneous rocks with the observed inclination ( $I_o$ ) in sediments (method 2). Method 2 assumes that the Earth's field is a geocentric dipole. Both methods assume that the secular variation is averaged out so that only averages for formations covering many tens of thousands of years may be used. There are errors ( $\alpha$ ) in determining  $I_e$  and  $I_o$  so the inclination error is itself subject to error. Because of the statistical inhomogeneity of the palaeomagnetic data a formal calculation of the error in  $\delta$  would be unrealistic,

but a lower limit is set by the  $\alpha$  values. In simple observations of fossil remanence  $\alpha$  is usually about  $10^\circ$ , whereas after the application of magnetic or thermal cleaning techniques accuracies of about  $5^\circ$  can sometimes be achieved.

Van Andel and Hospers<sup>2</sup> have compiled estimates of  $\delta$  using method 2. For the most part they used "old" observations without magnetic or thermal cleaning. They apply a "sign" test to their data which indicates a systematic positive bias. An alternative procedure is to sum their  $\delta$  values and study their scatter. Nineteen values calculated by van Andel and Hospers have a mean of  $+2^\circ$ , the standard deviation of the individual values is  $10^\circ$ , and the error in the mean (95 per cent) is  $5^\circ$ . (The first entry in their tabulation is omitted because of the very large uncertainty in restoring the igneous rocks in question to their original attitude.) Van Andel and Hospers reject two of their results in which the differences between declinations of igneous and sedimentary rocks are large. Omitting them from the calculations, the mean now becomes  $+3^\circ$ , the standard deviation  $10^\circ$ , and the error  $5^\circ$ . The mean inclination error does not depart significantly from zero, and the scatter in the observations is accounted for by random errors in estimating  $\delta$ .

Table 1. INCLINATION ERRORS IN SEDIMENTS

Core V20-108 <sup>11</sup>	+64	+66	+2
Core V20-109 <sup>11</sup>	+65	+62	+3

A closer look at the problem may be made from data based on demagnetization studies (Table 1), many of which have been published after the sources quoted by van Andel and Hospers<sup>2</sup>. There are four results (method 1) from Palaeozoic and Mesozoic rocks (red beds and varves) with a mean  $\delta$  of  $-3^\circ$ . There are seven results (method 2) from deep ocean sediments which cover the past  $2 \times 10^6$  yr. The V16 data are separated into normal and reversed polarities. In the V20 data the inclinations are lumped together irrespective of sign. They may be compared with the inclination expected from an axial geocentric dipole field which is the approximate field configuration observed in igneous rocks of this age; their mean  $\delta$  is  $+1^\circ$ . The individual estimates are distributed randomly about zero and differ from it by amounts comparable with the error in estimation.

It is therefore concluded that the analysis of van Andel and Hospers does not demonstrate a systematic inclination error in sediments as they claim it did. Moreover, results based on demagnetization work, and on which, as a consequence, most reliance can be placed, show no systematic error.

## Thickness and Viscosity of Etnean Lavas

THE thickness of a lava flow depends, in general, on three factors: the viscosity of the flowing lava; the angle of slope of the surface over which the lava is flowing; the local topography, that is, whether the lava is ponded in a depression or not. The thickness is seldom recorded by volcanologists, and even more seldom used as a tool (for example, in the interpretation of old volcanoes in which, owing to subsequent folding or tilting, the present attitude of the lavas may differ from the original attitude). No systematic study appears to have been made of the thickness and its relationship to the viscosity and angle of slope, and this communication, which records the results of a brief study recently made of the lavas of the Italian volcano, Etna, is a first attempt to explore this inter-relationship.

Etna was chosen for this study for the reasons that there are extensive spreads of young lavas on its slopes; these lavas are rather uniform in chemical composition (they are basaltic, near hawaiite: Rittmann, A., personal communication) and, it is supposed, in initial temperature and viscosity; eruptions take place quite frequently during which the viscosity can be determined; a great range of angles of slope is found, from  $0^\circ$  to  $>40^\circ$ ; there are numerous small quarries, road cuttings, and other sections in which the thickness of the young lavas may be measured. When the investigation was made, the 1966 eruption was still in progress, which allowed the viscosity of the lava to be determined.

There are certain difficulties in the measurement of a meaningful thickness of a lava flow. One is that most flows on Etna are compound, made of a number (sometimes a very large number) of separate flow-units; in this study the thickness of individual flow-units has been measured and recorded. Another difficulty is that lava channels which have been partially drained out are common on slopes steeper than about  $10^\circ$ , and the floors of such channels are much thinner than the levées on either side. For none of the eighty flow-units measured in this study is there any reason to suspect ponding of a lava in a topographic depression. All the measurements are on lavas on the southern and eastern slopes of Etna, nearly all of which are of aa type, and all are on young flows, most of which are historic lavas.

The graph in Fig. 1 shows the relationship between thickness and angle of slope. It can be seen that only on gentle slopes of less than  $7^\circ$  do lava flows more than 10 m thick develop, while no flow exceeding 5 m thick is found on a slope steeper than  $15^\circ$ . The considerable scatter of points on the graph, greatest at the low angle end, is probably a result of variations in viscosity. The viscosity of a flowing lava is least when it emerges from the vent: cooling, partial crystallization and loss of gases very quickly increase the viscosity and the resulting lava flow is correspondingly thicker.

The 1966 eruption of Etna, which began in mid-January, was still in progress in late May when this study was made. Lava was found to be flowing quietly from about five boccas (openings), and for the first few tens of metres below a bocca the lava typically flowed in a narrow stream 1-2 m wide between levées raised 1-1.5 m above the general level (Fig. 2). The angle of slope and velocity of flow were measured on eight different lava streams (see Table 1) and the viscosity derived from the formula

$$\eta = \frac{g \rho h^2 \sin \alpha}{3V}$$

where  $\eta$  = the viscosity in c.g.s. units (poises);  $g$  = 980.6 cm/sec<sup>2</sup>;  $\rho$  = density of flowing lava, taken as 2.0 g/c.c.;  $h$  = thickness of flow, in cm;  $\alpha$  = angle of slope, in degrees;  $V$  = velocity of flow, in cm/sec.

For the narrow streams just below the boccas, where the width of the stream is comparable with the thickness, and internal friction becomes significant, the formula

$$\eta = \frac{g \rho h^2 \sin \alpha}{4V}$$

is more appropriate (ref. 1).

The lowest values for viscosity were given by a pahoehoe flow which resulted when one of the levées of a lava stream a few metres below a *bocca* suddenly collapsed. The measurements were made hurriedly, but the value for viscosity that they give ( $0.4 \times 10^5$  poises) is believed to be more realistic than the  $0.7$  to  $0.8 \times 10^5$  poises given by the same lava stream where flowing between levées, in which the effect of internal friction by the walls may be greater than has been allowed for by the formula. In any event, the values recorded in Table 1 can be relied on only to give the correct order of magnitude of the viscosity.

Traced down the flow, the viscosity of a lava stream increases rather rapidly, and the highest value ( $1.5 \times 10^7$  poises) was measured on a flow-front about 500 m below the *bocca*. The viscosity at which flow virtually ceases (a flow rate of  $10^{-3}$  cm/sec, that is, rather less than 1 m/day, has been chosen) is plotted on the inset to Fig. 1 for different thicknesses and angles of slope, and lies between  $10^9$  and  $10^{11}$  for most Etnean lavas.

Three observations which have a bearing on the structure and thickness of lava flows were made on the 1966 lava field. One concerns the life and size of a flow-unit. Most of the *boccas* from which lava was flowing were

\* Lava flowing in narrow channel (between levées), for which a different formula is used (see text).

† Pahoehoe flow resulting from burst levée.

FF, Flow front; otherwise all measurements are of the movement of the top surface of lava streams.

Flow 1 measured on May 22; 2-5 on May 24; 6 on May 27; and 7-8 on May 29, 1966.

secondary, being fed by lava tunnels the course of which could be traced by fumaroles at the surface. The *boccas* proved to be very impersistent. As one ceased to erupt lava, it was replaced by the appearance of another. No *bocca* erupting on the first day of observation was still erupting seven days later. Not only did the location of active *boccas* change, but also the lava streams from each *bocca* changed in position. During the period of observation, several streams were seen to be born, and as many were seen to die by ceasing to flow. It was estimated that about five substantial flow units, each with a volume of the order of  $10^3$  to  $10^5$  m<sup>3</sup>, were added to the lava field per day (the total rate of production of lava being about 1 m<sup>3</sup>/sec), plus a considerable number of smaller units. Thus the 1966 lava field must be built up of hundreds or even thousands of flow-units. Such compound flows are so common on basaltic volcanoes that they should be regarded as characteristic of basaltic eruptions.

A second observation was that there are certain minimum dimensions, best termed "minimum viable dimensions", for a lava stream that is able to flow for a considerable time (a day or more) and to reach a considerable distance from the *bocca*, as distinct from a stream that flows for only a short time and reaches only a short distance from the *bocca* before congealing. The minimum viable thickness on a slope of  $10^\circ$ - $20^\circ$  proves to be about 60 cm for the 1966 Etna lava, and the minimum cross-sectional area of a viable lava stream on the same slope about 1.2 m<sup>2</sup>. These minimum viable dimensions are for lava of viscosity close to  $4 \times 10^4$  poises; the viable dimensions are likely to be smaller for less viscous lavas, such as the basaltic lavas of Hawaii, and greater for more viscous lavas, such as the andesitic and rhyolitic lavas of other volcanoes. The minimum viable thickness for Etnean lavas on different slopes is probably given by the lower curve of Fig. 1 (assuming that none of the lava flow-units measured for the construction of Fig. 1 were impersistent, non-viable units, thinner than the minimum viable thickness).

A third observation was that a ropy, pahoehoe-type, lava surface was preserved only on flows within a few tens of metres of a *bocca*. The data in Table 1 suggest that the corresponding limiting viscosity is about  $2 \times 10^5$  poises; with higher viscosity, a surface of aa type developed instead.

I am grateful to J. E. Guest and G. J. Jones, Dr. R. R. Skelhorn and Professor Trausti Einarsson for critically reading the manuscript.

## THE SOLID STATE

## Formation of "Hollow Whiskers" from Metals by Reaction with Ferricyanide and Ferrocyanide

WHILE devising a microscopic test for the detection of small particles of metallic iron it was discovered that blue whisker-like structures (Fig. 1) were formed from iron particles or iron alloys in a 10 per cent (w/w) solution of acidified (0.06 N hydrochloric acid) potassium ferricyanide. Further microscopic examination of these structures revealed them to be hollow tubes. Considerable branching of these tubules was also evident, giving a general appearance not unlike that of fungal mycelium. Growth of these tubules proceeds at the tip, and the rate of growth, the diameter of the tubules, the amount of branching and shape of the tubules appear to be directly related to the concentration of ferricyanide and the type of iron alloy. With powdered iron, for example, in a 10 per cent concentration of acidic ferricyanide, the tubules vary from about 4 to 10  $\mu$  in diameter. They may grow outward from the iron particles to a distance of from 0.1 to 0.5 mm or longer within a second. In less than 30 sec most of the tubules have formed, many of them bent or looped, or both. At a ferricyanide concentration of 5 per cent (w/w) the tubules are more variable, larger in diameter, and grow much longer. At concentrations of 2-2.5 per cent the tubules grow more slowly, some of them forming a blue precipitate at the end which slowly drifts away giving the appearance of smoke coming out from a lengthening smokestack. At concentrations of 20 per cent (w/w) and higher, a few tubules may be seen but mostly blue hemispherical and spherical structures are formed on the surface of the iron. If the solution is then diluted, tubules may be seen to arise from these structures. The tubules formed from acidic ferrocyanide and iron appear to be lighter blue or green in colour.

Among the metals examined so far, tubules have been formed from zinc, cadmium, nickel, cobalt, lead, tin, chromium and copper with either acidic ferricyanide, ferrocyanide or both. The tubules from chromium and cobalt may often appear red or pink in colour while those from copper appear reddish brown with ferricyanide. In general, with the exception of cadmium and iron, the tubules are quite contorted and short (< 0.2 mm). Since copper is on the noble side of hydrogen in the electromotive series, it is necessary to make it anodic by means of an applied voltage, before the tubules appear.

Preliminary studies with some alloys in the form of wires have indicated that the tubules generally appear

Fig. 1. Production of tubules from a particle of iron powder in an acidified (0.06 N hydrochloric acid) solution of 10 per cent potassium ferricyanide solution. ( $\times c. 135$ .)

Fig. 2. Tubules formed from bend in nichrome wire in acidified 10 per cent potassium ferricyanide solution. ( $\times 10$ .)

to arise from portions of the metal which have been stressed by bending (Fig. 2). The various metallic components of the alloys, providing they react with the ferricyanide or ferrocyanide to form an insoluble complex, appear to produce their own distinct tubules as indicated by a difference in morphology and colour (Fig. 3). The concentration of reagents necessary for producing tubules appears to vary somewhat for each metal and for the same metal in different alloys.

In general, "hollow whiskers" or tubules seem to be produced by any metal which forms an insoluble complex with ferri- or ferro-cyanide. The following tentative mechanism for the formation of these tubules is suggested. When the acidified solution of ferricyanide comes in contact with the metal, the electrons from the metal,  $M \rightarrow M^{++} + 2e$ , react with the hydrogen ions to form atomic or molecular hydrogen at the surface,  $2e + 2H^+ \rightarrow 2H \rightarrow H_2$ . Removal of the electrons causes the metal to pass into the ionic form (the reaction is displaced to the right). The same results may be obtained (removal of the electrons) in a neutral solution of ferricyanide if the metal is made anodic by an applied potential. The areas where the metal forms ions may be called point anodes. When the metal ions first come into contact with the ferricyanide they react to form an insoluble complex and a hemispherical dome may be first formed. If the concentration of ferricyanide is sufficiently high, such domes are produced and indicate a membrane of the metal ferricyanide complex which is very "tough" and which resists the pressure of the ions coming from the point anode. If the concentration of ferricyanide is low the pressure of the ions is sufficiently great to overcome the lower membrane strength of the complex and the ions break through, leading to the formation of a hollow cylinder. More metal ions flow along the tubules to form a metal ferricyanide complex on coming into contact with the ferricyanide at the tip. The end result appears to be a series of metal ion tracks which originate from the many point anodes along the metal surface.

Such "hollow whiskers" but of greater size (0.2-0.4 mm in diameter and up to 90 mm in length) were observed in 1958 (ref. 1) from iron in rapidly flowing warm water (55° C) containing calcium bicarbonate in an amount insufficient for complete corrosion. Apart from the fascination of these "bio-like" structures, there appear to be many practical applications of this phenomenon which immediately suggest themselves. In metallurgy, it may provide a tool for quick determination, qualitative and possibly quantitative, of various elements in an alloy. By applying an increasing positive potential to the alloy, metal ions may be "pulled out" in succession in the characteristic form of their ion tracks or tubules. It may

Fig. 3. End of tubules formed in acidified 10 per cent potassium ferri-cyanide solution. Tips are pink or light red, presumably due to a chromium ferri-cyanide complex, while remainder of tubule is blue-green due to the ferrous ferri-cyanide complex. ( $\times c. 135$ .)

also afford a valuable tool for the study of stress and stress cracking corrosion since the tubules appear to arise most easily at stressed points. A quick method for the determination of corrosion resistance of alloys may be afforded as well as a quick screening method for corrosion inhibitors. The voltage required for cathodic protection might also be rapidly determined by observing the potential at which whisker formation is prevented.

## PHYSICS

### Extinct Radioactivity and the Discovery of a New Pleochroic Halo

BECAUSE of the cosmological implications of such a discovery<sup>1</sup>, considerable effort has been expended toward the detection of extinct radioactivity in crustal rocks and meteorites. An excess of fissionogenic xenon isotopes in the Fayetteville meteorite<sup>2</sup> and the presence of excess fission tracks in the Toluca meteorite<sup>3</sup> have in each case been considered possible evidence of spontaneous fission from the extinct nuclide plutonium-244. Although an earlier search for the neptunium series in nature failed to reveal its existence<sup>4</sup>, later results suggest that it may exist<sup>5</sup>.

The investigation of pleochroic haloes (minute regions of structural disorder which occur in various minerals as a result of prolonged alpha emission from microscopic radioactive inclusions) is usually related to the determination of the age of a mineral or to the question of the invariance of the decay constant over geological time<sup>6,7</sup>. Henderson also discussed extinct  $\alpha$  radioactivity relative to this phenomenon<sup>8</sup>, and haloes were found which could be attributed to various polonium isotopes. Previously, it was assumed that all polonium haloes originated from radioactive hydrothermal solutions containing equilibrium amounts of decay products from the uranium-238 series<sup>9</sup> and thus did not constitute evidence of extinct radioactivity from the cosmological point of view. A recent study of polonium haloes indicates this conclusion may not be valid<sup>10</sup>.

The purpose of this communication is to report the discovery of a new type (subsequently designated as type Y) of pleochroic halo which was found in Canadian Pre-Cambrian biotite. Two haloes of Y type have been found

in close proximity (Fig. 1), and the halo radii are about  $26.5 \pm 0.5\mu$  assuming a negligible correction for the size of the central inclusion. Combining previous measurements of the radii of haloes from uranium-238 and thorium-232<sup>11,12</sup> with my own results, a fairly accurate range-energy curve (Fig. 2) may be established for this mica. From Fig. 2 it is found that the Y haloes were produced by  $\alpha$  particles of approximately  $6.55 \pm 0.05$  MeV. These Y haloes exhibit a rather light coloration, thus implying that only a relatively small amount of  $\alpha$  activity existed originally in the central inclusion or that the parent nuclide decayed partially by  $\beta$  emission.

In attempting to ascertain the parent nuclide of the Y haloes it is natural to try to correlate the ring structure with that of the well known uranium or thorium haloes. In each case the progenitors of these haloes (that is, uranium-238 and thorium-232), however, are low energy  $\alpha$  emitters giving rise to small inner rings which are not present in the Y haloes. Furthermore, the development of the outer rings of the uranium and thorium haloes follows  $\alpha$  particle emission from the respective daughter products. Uranium and thorium haloes (Figs. 3 and 4) have been observed in the embryonic stage (where only the first ring is visible), the intermediate stage (where nearly all rings are visible), and the overexposed stage (where the inner rings are too dark to be discerned and only the outer rings are plainly visible). In none of these cases do the uranium or thorium haloes resemble the Y haloes, either with respect to halo radii or ring struc-

Fig. 1. Type Y halo ( $\times 375$ ).

Fig. 2. Range-energy curves for Canadian mica. —, Experimental; ----, extrapolated.

ture. Also, by using the HF technique of etching with hydrofluoric acid for detecting fission fragment tracks in mica<sup>13</sup>, it can be shown that the central inclusions of the Y haloes do not contain any significant amounts of spontaneous fissionable nuclides such as uranium-238. An acid etch of this mica revealed no fission tracks which emanated from the central inclusions of the Y haloes whereas a cluster of fission tracks is always present in the uranium-238 haloes (Fig. 5).

The chart of the nuclides reveals a few  $\alpha$  emitters of approximately the required energy in the trans-uranium region (for example, einsteinium-252) and several in the trans-lead region (for example, radium-222, francium-211, polonium-217, bismuth-211). The emitters in the trans-uranium region may be ruled out for the same reason as were uranium-238 and thorium-232, namely, any halo which develops from the trans-uranium nuclides would exhibit many rings because of subsequent daughter  $\alpha$  decay. Some  $\alpha$  emitters in the trans-lead region may be excluded for the same reasons. Although it is not possible to identify the parent nuclide of the Y haloes unequivocally, it is felt that bismuth-211 represents a reasonable choice because of the  $\alpha$  energy of bismuth-211 and the fact that no other rings are to be expected from subsequent decay. If these haloes are caused by the  $\alpha$  decay of bismuth-211, they represent an actinium series analogue to the polonium haloes of the uranium-238 series. Polonium haloes from polonium-210 (Fig. 6), polonium-214 and polonium-218 have been found<sup>19</sup> independent of

Fig. 5. Fission tracks from embryonic uranium halo.

Fig. 6. Polonium-210 halo near conduit ( $\times 375$ ).  $\pi = 18.6\mu$ .

Fig. 3. Uranium halo ( $\times 375$ ).

Fig. 4. Thorium halo ( $\times 375$ ).

uranium or thorium haloes, and in one case a ring from bismuth-212 occurs in a polonium halo. As was the case for the Y haloes, an acid etch of the polonium haloes revealed the absence of fission tracks from the central inclusions. To obviate the possibility that some metamorphic heating event had annealed the fission tracks in the mica, polonium haloes and uranium haloes were irradiated with a thermal neutron flux of  $10^{17}$  neutrons/cm<sup>2</sup>. Subsequent etching of the mica revealed a vastly increased number of fission tracks in the uranium haloes and no tracks whatsoever from the polonium haloes.

What relation, if any, these new haloes bear to the recently reported giant pleochroic haloes<sup>14</sup> is not known at this time. There seems to be little doubt, however, that the  $\alpha$  radioactivity responsible for the formation of the giant haloes and the Y haloes corroborates the evidence for extinct radioactivity of short half-life previously found in polonium haloes<sup>10</sup>. Further evidence of  $\alpha$  radioactivity of unknown origin has now been found in the black Ytterby mica<sup>15</sup>. It is difficult to reconcile these various types of extinct radioactivity with the current theories of nucleosynthesis and crustal formation<sup>16,17</sup>. The recent discovery of haloes<sup>18</sup> in the Wolsendorf fluorite (due to the sequence of emitters francium-219, astatine-215 and bismuth-211) further substantiates the identification of the Y halo with bismuth-211.

I thank Drs. H. B. S. Cooke, C. G. I. Friedlaender, E. W. Guptill, and G. C. Milligan of Dalhousie University, Halifax. I also thank Dr. J. H. J. Poole, Trinity College, Dublin, for making available various samples of mica which contained haloes. Facilities at the Oak Ridge National Laboratory were made available through the

courtesy of Dr. A. E. Cameron and Mr. Rodger Neidigh. I also thank Drs. C. L. and A. M. Thrash, Columbus, Georgia, for financial assistance.

### Thermosolutal Convection: Observation of an Overstable Mode

THE character of small amplitude convection in a fluid which has been subjected to a stabilizing gradient of some solute and a destabilizing temperature gradient has been calculated by Gershuni and Zhukhovitskii<sup>1</sup>, Veronis<sup>2</sup> and Sani<sup>3</sup>. Gershuni and Zhukhovitskii considered an infinite vertical layer of fluid, in which the flow varied in only one (horizontal) direction, while the other authors considered a horizontal layer in which flow was two-dimensional. All these treatments show that convection can begin either as a steady motion or as infinitesimal oscillations, depending on the conditions. In the case of overstability, Sani predicts that the amplitude of oscillations would be very small, while Veronis suggests that they would readily lead to a steady flow.

The treatment of Gershuni and Zhukhovitskii is physically so unrealistic that the results are primarily of qualitative interest. Experimental verification of the calculations of Veronis and Sani is also hampered, though to a lesser extent, because both authors assume ideal conditions of hydrodynamic freedom, with temperature and concentration constancy, at both horizontal boundaries. Nevertheless, the physical cause of overstability in this system is that the heat and the solute have different diffusivities, so that a change of boundary conditions is unlikely to affect its behaviour qualitatively.

The theoretical treatments assume that the undisturbed temperature and concentration gradients are constant throughout the fluid. Although it is possible to come quite close to this thermal condition in experiments, the establishment of a steady diffusive flux of solute is difficult because of the impermeability of most materials of which the upper and lower boundaries might be constructed. Nevertheless, the slowness of the diffusion process allows the establishment of transient temperature and concentration profiles which are markedly non-linear and yet sufficiently static for experiments to be performed. Turner and Stommel<sup>4</sup> have described experiments in which a tank of water containing salt in a solution in which the concentration increased downwards was heated from below, resulting in the formation of convecting layers. Because the boundaries of the liquid were impermeable to salt, the concentration profile was a transient, non-linear one. Although few details were given, it seems likely that the temperature profile was also non-linear owing to transient heating and perhaps to heat loss from the side walls.

In an investigation of the onset of convection in the first, that is the bottom layer in a system similar to that of Turner and Stommel, an oscillatory effect has been observed which is presumably the overstability predicted by the theories mentioned above.

The liquid used was water, with sugar as the solute. Two thermocouples were formed at the junctions of fine horizontal copper and Constantan wires, near the centre and respectively 0.5 and 1.0 cm above the bottom of the liquid, which was 9.7 cm deep. The differential output of these thermocouples was amplified and displayed on a strip chart recorder. As heating progressed the temperature difference increased, and the record was kept on scale by adding progressively larger microvoltages from a Tinsley vernier potentiometer in series with the thermocouples.

The records obtained in such an experiment are shown in Figs. 1 and 2. Fig. 1 is a graph of concentration gradient versus depth, measured by a scanning schlieren method before heating began. The gradient of this graph, that is the second derivative of concentration with respect to depth, is nowhere sufficient to produce a significant change in solute distribution by diffusion during the experiment, so that Fig. 1 represents closely the solute distribution at marginal stability. Fig. 2 shows the temperature record near marginal stability, the temperature gradient indicated at this stage being approximately 2° C cm<sup>-1</sup> near the bottom of the liquid. The heating rate was increased slightly at the point marked A, while at that marked B the sensitivity of the recorder was reduced by a factor of 50. As marginal stability approached, the record became increasingly noisy. The appearance of a definite oscillation was followed by a rapid growth of its amplitude, and after about 12 min it became increasingly disordered. About the time that the oscillation became large, that is just after B, schlieren observation showed several small cells about 0.7 cm high at the bottom of the liquid. These cells were initially separate from one another, but the number increased with time to form a fairly continuous layer. The height of the cells increased slowly to about 1.0 cm 5 min after they were first observed, at which stage they were about 1.5 cm wide at the base.

The features of this effect which can readily be checked against theory are the temperature gradient required to

Fig. 1. Profile of the solute concentration gradient. The equivalent isothermal density gradient values are also shown.

Fig. 2. Section of the temperature record near marginal stability. The quantity plotted against time is the differential output of two copper-Constantan thermocouples placed 0.5 and 1.0 cm above the tank bottom. Heating rate was increased slightly at A. Left-hand voltage scale applies up to B, right-hand scale thereafter.

produce the oscillation in the presence of the particular concentration gradient, and the period of the oscillation. Both Veronis and Sani predict that the critical condition for overstability in this case is very nearly

$$R = \frac{\nu}{K + \nu} R' + 657$$

$$\text{where } R = \frac{g \Delta \rho_i h^3}{\nu K \rho}$$

$$\text{and } R' = \frac{g \Delta \rho_c h^3}{\nu K \rho}$$

Here  $g$  = acceleration due to gravity,  $\rho$  = density,  $\Delta \rho_i$  = density difference produced thermally over the convecting depth,  $\Delta \rho_c$  = density difference caused by the concentration gradient over the convecting depth,  $h$  = convecting depth,  $\nu$  = kinematic viscosity,  $K$  = thermal diffusivity. The value 657 results from the ideal boundary conditions assumed. More realistic boundary conditions would probably raise this value.

Taking 0.7 cm as the convecting depth,  $3 \times 10^{-4} \text{ C}^\circ$  as the expansion coefficient of the solution,  $2 \text{ C}^\circ/\text{cm}$  as the temperature gradient,  $0.01 \text{ cm}^2/\text{sec}$  as the viscosity and  $0.0014 \text{ cm}^2/\text{sec}$  as the thermal diffusivity,  $R' \approx 8,200$  and  $R \approx 9,900$ . The value predicted for  $R$  is about 8,000. Since the critical values of  $R$  predicted by Veronis for the onset of an infinitesimal steady motion and the most favoured finite amplitude steady motion are about 80,000 and 1,200 respectively for this value of  $R'$ , the experimental value clearly agrees best with the value predicted for overstability.

The period predicted by both Veronis and Sani for this case is about 45 sec, which is not markedly different from the observed period of 55 sec.

*Note added in proof.* I am grateful to Dr. D. Nield of the University of Auckland for the interest he has shown in this project. He has made available to me a copy of his recent Ph.D. thesis which contains an analysis of the small-amplitude three-dimensional thermosolutal convection problem for rather general boundary conditions. The evaluation of the critical conditions for overstability in any but the ideal case mentioned above appears to be very tedious, and quantitative results applicable to the present observation are not at present available. However, for ideal boundaries, the values calculated for this case for both  $R$  and the period are the same as those given by the two-dimensional analyses mentioned above.

## CHEMISTRY

### Adsorption of the Three Hydrogen Isotopes on Charcoal

PREVIOUS studies on hydrogen isotope adsorption on charcoal have been confined to hydrogen and deuterium<sup>1</sup> and show the variation that would be expected from the physical nature of the adsorbent. As part of a general study on isotope effects we have extended this work to include tritium.

The apparatus was of the conventional type for gas adsorption studies, with minimum free gas volumes to ensure maximum accuracy. The charcoal was "granulated activated for gas adsorption" grade supplied by Rubber Industries and Sherman Chemicals, Ltd., and the hydrogen isotopes were 99.95 per cent pure  $\text{H}_2$ , 99.0 per cent  $\text{D}_2$ , 98.4 per cent  $\text{T}_2$ . Protium was the only impurity in the heavier isotopes.

The charcoal samples were thoroughly outgassed *in vacuo* at  $580^\circ \text{C}$  before the start of measurement. The volumes of gas adsorbed,  $V_a$ , were calculated by PVT methods (in standard ml./g) for a series of hydrogen isotope equilibrium pressures,  $P_e$ , at liquid nitrogen temperature. Plots of  $P_e/V_a$  against  $P_e$  for all three isotopes are good straight lines at pressures greater than 100 mm or so, as shown in Fig. 1, indicating that the adsorption follows the Langmuir isotherm<sup>2</sup>, for which

$$P_e/V_a = 1/V_m b + P_e/V_m \quad (1)$$

The weighted means for the slopes,  $s$ , and intercepts,  $i$ , of curves like Fig. 1 are summarized with their standard deviations in Table 1, together with calculated values for  $V_m$ , the volume of gas adsorbed per g of charcoal for monolayer coverage.

The values of  $V_m$  decrease in the sequence  $\text{T}_2 > \text{D}_2 > \text{H}_2$  and are  $\sim 120$  standard ml./g. The parameter  $b$  represents the ratio of the number of molecules which strike and stick to the surface per unit area and pressure to the number of adsorbed molecules which escape per unit area from a saturated surface; the values are identical within the experimental error at  $0.012 \text{ (mm Hg)}^{-1}$ . The isotope effect on adsorption appears to arise principally because of changes in monolayer volume ( $V_m$ ) rather than the adsorption-desorption energetics ( $b$ ). This is unexpected, for  $V_m$  should be a function of molecular size, which is almost identical for the three isotopic molecules, whereas molecular attraction forces and isotopic masses should affect  $b$ , which is given by

$$b = \frac{\alpha e^{q/kT}}{k_0 (2\pi m kT)^{0.5}} \quad (2)$$

where  $\alpha$  is the sticking coefficient,  $q$  the heat of adsorption and  $k_0$  the temperature independent factor for the desorption process (see ref. 2, page 64). The slightly larger heat of adsorption for the heavier isotopes ( $q_{\text{D}} - q_{\text{H}} = 180 \text{ cal/}$

Fig. 1. Langmuir isotherm for tritium at  $77^\circ \text{K}$ . Vertical axis ( $P_e/V_a$ ) in units of mm Hg/standard ml. per g; horizontal axis ( $P_e$ ) in mm Hg. ●, Run 10; ○, run 11.

Table 1. ADSORPTION ISOTHERM AT 77° K

Isotope	$s \times 10^3$	$i$	$b \times 10^3$ (mm Hg) <sup>-1</sup>	$V_m$ std. ml./g
H	9.439 ± 0.07	0.7434 ± 0.0342	1.270 ± 0.059	106.0 ± 0.8
D	8.385 ± 0.019	0.7230 ± 0.0058	1.160 ± 0.010	119.3 ± 0.3
T	7.380 ± 0.043	0.6060 ± 0.0147	1.218 ± 0.030	135.8 ± 0.8

mole, ref. 2) is partly balanced by the mass effect. The  $\alpha$  and  $k_0$  terms contain entropy factors which may vary with isotopic mass though the magnitude of the variation is not calculable.

The isotope effect on  $V_m$  and  $b$  may be explained if more energetic (and therefore less favourable) adsorption sites are available to the heavier molecules because of their higher heats of adsorption. This would not only result in the observed  $V_m$  sequence but would reduce the average heat of adsorption for the heavier isotopes, thus minimizing the effect of the energy term in equation (2).

The isotope effect on adsorption found in this work is comparable with that of 8 per cent found by Van Dingenen<sup>1</sup>.

A high pressure experiment using hydrogen at 1.5° C also conformed with the Langmuir isotherm with  $b = 1.71 \times 10^{-5}$  (mm Hg)<sup>-1</sup> and  $V_m = 35$  standard ml./g. The heat of adsorption for hydrogen on charcoal, calculated from equation (2) with the assumption that  $\alpha$  is independent of temperature, is 1.3 kcal/mole, in excellent agreement with the values of 1.0–1.8 kcal/mole found by Van Dingenen<sup>1</sup>.

### Step Increase of the Carrier Gas Inlet Pressure in Gas Chromatography

UNTIL now pressure variation has been treated with great care in gas chromatography. Most experiments are carried out in equilibrium conditions, with more or less carefully controlled inlet pressure, and recently interest has been focused on the use of pressure programming<sup>1,2</sup>. In spite of the development of an exponential pressure programmer<sup>3</sup> only slow rates of pressure programming have been used. For theoretical as well as practical reasons, we suggest the use of extremely high programme rates, so that when the injection is made, the inlet pressure is increased almost instantaneously from a value near that of the outlet pressure up to the final value. Clearly, the duration of the programme will be much less than that of the analysis itself. This method has, however, distinct advantages over the more conventional ones.

A rigorous theory of programmed pressure gas chromatography has not yet been published, although some approximate results had been reported<sup>3,4</sup>. These were based on the postulate that the column is always in equilibrium conditions, that is, at a given time  $t$ , the inlet pressure  $p_i$  and outlet velocity  $u_0$  are related by the classical equation

$$u_0 = \frac{k}{2Lp_0} (p_i^2 - p_0^2) \quad (1)$$

This approximation is acceptable only for very low programme rate because there is a time delay between any inlet pressure variation and the time when the outlet flow velocity reaches the value given by equation (1). Furthermore, even at low programme rate the carrier gas mass flow rate is not constant along the column; gas accumulates in the column because at equilibrium the hold-up of carrier gas is proportional to the product of average pressure and corrected air retention volume<sup>5</sup>.

All these phenomena can be accounted for by writing the mass-balance in a differential section of the column and combining this equation with the Darcy's equation which is valid in the flow velocity range useful in gas chromatography<sup>5</sup>. The general equation

$$\frac{\partial p}{\partial t} - \frac{K}{2\eta\epsilon} \frac{\partial^2}{\partial x^2} p^2 = 0 \quad (2)$$

cannot be solved for the limit conditions in which the outlet pressure is constant and the inlet pressure variable. Distribution theory leads us to consider what happens when the inlet pressure is suddenly increased from  $p_0$  to a given value,  $p_i$ . The pressure profile in the column can be calculated at any instant after the pressure step. Numerical calculations have been made by Aronofsky<sup>6</sup>, using reduced values of column length ( $x/L$ ).

pressure ( $p/p_0$ ) and time ( $\frac{Kp_s}{\eta\epsilon L^2} t$ ). Using Darcy's law

$$u = -\frac{K}{\eta} \frac{\partial p}{\partial x} \quad (3)$$

velocity profiles can be calculated from pressure profiles (Fig. 1). The gas velocity profiles change rapidly with time. This variation is caused by the surge of gas in the empty column after the step increase in the inlet pressure and by the dampening action of column pneumatic resistance. A pressure gradient wave moves along the column. This is not a shock wave because in gas chromatographic conditions the process is isothermal and not adiabatic. This wave cannot by itself transport matter, but it causes large gas velocities near the inlet of the column for some time.

Fig. 1. Carrier gas velocity profiles in the column at various times after an instantaneous increase of the inlet pressure. Variation of the reduced velocity (ratio of the velocity  $u$  at a given time and point to the outlet velocity at infinite time  $u_0$ ) against reduced column length ( $x/L$ ) for different values of the reduced time.

Table 1. COMPARISON OF RESULTS OBTAINED AT EQUILIBRIUM AND WITH STEP INCREASE OF INLET PRESSURE

Compound	$k'$	$p_i = 6$ atm (absolute)					$p_i = 8$ atm (absolute)					$p_i = 11$ atm (absolute)				
		Equilibrium $t_R$ (min)	$t_R$ $W$	Non- equilibrium $t_R$ (min)	$t_R$ $W$	$\Delta t(\%)$ $t_{Req.}$	Equilibrium $t_R$ (min)	$t_R$ $W$	Non- equilibrium $t_R$ (min)	$t_R$ $W$	$\Delta t(\%)$ $t_{Req.}$	Equilibrium $t_R$ (min)	$t_R$ $W$	Non- equilibrium $t_R$ (min)	$t_R$ $W$	$\Delta t(\%)$ $t_{Req.}$
Methane	0	17		10.5		38	12.6		8.0		48					
Isopentane	0.24	21.8	138	15	92	30	15.7	107	9.8	72	37	11.0	100	6.0	53	45
<i>n</i> -Pentane	0.32	22.5	132	16.5	96	27	16.7	113	10.7	70	36	11.6	85	6.6	55	43
<i>n</i> -Hexane	0.61	30.8	131	22.1	82	27	22.8	110	16.5	70	28					
2,4 Dimethyl pentane	1.15						27.0	101	19.8	72	27					
Resolution $t_C/t_n C_s$		8.1		8.0			7.7		5.8			4.7		4.3		

It is remarkable that the profiles have a shape which is opposite to that of the equilibrium profiles obtained at an infinite value of time, since the concavity is in the reverse direction. In conventional slow flow rate programming, on the contrary, the pressure and velocity profiles are not very different from the equilibrium profiles.

In conventional analysis, peaks migrate much more slowly at the beginning of the column than near the outlet. The gas surge in the column which is caused by the pressure step leads to flow rates at the beginning of the column which are much higher than those encountered in equilibrium conditions. The analysis will thus be shortened.

It would be useless, of course, to shorten the analysis time if the resolution was largely decreased. From the pressure and velocity profiles a certain loss of efficiency may be anticipated. Since at the beginning of the column the velocity will be much higher and the pressure only somewhat lower than in equilibrium conditions, the height equivalent to a theoretical plate will probably be increased somewhat.

Experiments were made with an open tube column, 140 m long, 0.25 mm in diameter, at 56° C, using a flame ionization detector. Outlet pressure is atmospheric. Squalane is the stationary phase, with an average film thickness of 0.3  $\mu$ . The same mixture of linear and branched

paraffins was used in all experiments, with values of  $k'$  which vary from 0.25 to 1.15 allowing investigation of the results of this new method with compounds which have a sizable retention. The optimum flow rate for *n*-hexane corresponds to an absolute inlet pressure of about 4 atm.

Fig. 2 shows two of the chromatograms obtained during the experiments reported here. Chromatogram 2a was obtained in equilibrium conditions with a constant inlet pressure of 8 atm. absolute. Chromatogram 2b was obtained by injecting the mixture at a low inlet pressure (1.2 atm. absolute); immediately after injection the inlet pressure was raised to 8 atm. absolute. The retention times are much lower in chromatogram b than in a. The relative time reduction decreases with increasing  $k'$ , as might be predicted, but the resolution seems to be much the same in each case. Table 1 gives retention times in both experiments together with the results obtained at different values of inlet pressure and with data on relative peak thickness and time-based resolution, although we understand from Halasz and Deininger that volume-based resolution would be a more relevant parameter.

In addition to reducing the analysis time with only a small loss in resolution, this method has some other distinct advantages. Very high inlet pressure can be used without any injection problems; injection can be made with a very low differential pressure acting on the septum (0.1 atm. or less), and before increasing the pressure a metal plug can be screwed on to prevent any leak. In addition to the pressure controller only a two-way valve (such as a toggle valve) is needed, which makes experiments very easy to carry out. The detector, however, must accept a fast variation of carrier gas flow rate without any important base line drift. This is not a problem in the case of capillary columns but is a serious one for conventional packed columns.

One or several pressure steps can be made, or a step may be combined with a more conventional pressure programme. It must be emphasized, however, that the largest time reduction is obtained when the pressure variation occurs in only one step. Knowledge of the flow velocity and pressure at any time and point in the column allows peaks, retention times and base width to be calculated. This, however, requires considerable computational work and will be reported later. We thank Jean Merle D'Aubigne and Madame Monique Jacques for their help in performing the experiments.

### 5-Benzyl-3-furylmethyl Chrysanthemate: a New Potent Insecticide

FOLLOWING earlier work<sup>1</sup>, we have synthesized more non-ketonic esters of chrysanthemic acid. One new compound, 5-benzyl-3-furylmethyl (+)-*trans*-chrysanthemate (I), is fifty-five times as toxic to adult female *Musca domestica* L. (house-flies) as the mixed esters of the natural pyrethrins, nearly three times as toxic as parathion and more than five times as toxic as diazinon. The same ester is ten times as toxic to adult *Phaedon cochleariae* Fab. (mustard beetles) as the natural pyrethrins and thirteen times as toxic as parathion. The (±)-*cis-trans*-chrysanthemate (m.p. 43–48°) is the most toxic compound tested so far, of any class of insecticide, to 1–2 day old unfed females of *Anopheles stephensi* and *Aedes aegypti* (results provided by Dr. A. B. Hadaway). This insecticidal activity is greater than has been found before in a compound containing only carbon, hydrogen and oxygen. By contrast, its acute toxicity to mammals seems to be small; for example, the median lethal dose to female rats for the (±)-*cis-trans*-chrysanthemate administered orally is between 600 and 800 mg/kg (personal communication from Dr. J. M. Barnes).

† Relative potencies were derived from  $LD_{50}$  values for the compounds and 5-benzyl-3-furylmethyl (±)-*cis-trans*-chrysanthemate (taken as standard and given potency 100) in simultaneous comparisons. Drops (1  $\mu$ l.) of the compounds dissolved in acetone were applied topically from a micrometer syringe (ref. 5) to 3–4 day old adult females (*Musca*) or adult males and females (*Phaedon*).

‡  $LD_{50}$ , 0.016  $\pm$  0.0003  $\mu$ g/female fly.

§ At 1 : 1 compound : piperonyl butoxide ratio.

¶  $LD_{50}$ , 0.0007 per cent w/v.

Previously<sup>1</sup>, high toxicity to insects was found in chrysanthemates in which a planar activating nucleus (cyclopentenolone in the natural pyrethrins and allethrin, benzene in the benzyl esters<sup>1</sup>) held an unsaturated side chain in an appropriate stereochemical relationship to the acid. The best compound in the earlier series was 4-allyl-2,6-dimethylbenzyl (+)-*trans*-chrysanthemate (II).

and mustard beetles, so furfuryl and 3-furylmethyl chrysanthemates were investigated systematically. Methyl groups increased the activity of otherwise unsubstituted compounds, but they diminished toxicity when a benzyl group was present. The change from 5-benzylfurfuryl chrysanthemate to 5-benzyl-3-furylmethyl chrysanthemate dramatically increased the insecticidal activity and even the (±)-*cis-trans*-chrysanthemate (Table 1) was more than twenty times as toxic to house-flies as the natural pyrethrins.

Table 1 compares the activities of some of the compounds synthesized with those of the natural pyrethrins and of some other insecticides. The (–)-*trans*-chrysanthemate and (+) and (–)-*cis* chrysanthemates are less active than the (+)-*trans*-ester, and introducing a 2-methyl group into the 5-benzyl-3-furylmethyl ester decreases activity to both insect species. Although less toxic than the (+)-*trans*-chrysanthemate, 5-benzyl-3-furylmethyl (+)-*trans*-pyrethrate (prepared using the naturally derived crystalline acid chloride<sup>2</sup>) had a somewhat better knockdown power 10 and 15 min after treatment and killed more house-flies after 24 h than the same dose of pyrethrum, when tested by a topical application technique<sup>3</sup>.

Piperonyl butoxide barely synergized the most active esters at a toxicant : synergist ratio of 1 : 1; this may be because the insect cannot readily detoxify the most potent compounds in this series and so activity is not enhanced if the synergist interferes with detoxification mechanisms.

Details of these compounds, of the methods of synthesis, and of the biological tests will be published elsewhere. 5-Benzyl-3-furylmethyl alcohol was conveniently obtained by the following route from  $\delta$ -phenyl laevulic ester<sup>4</sup>.

The furan ring is close in size to a cyclopentenolone, so furfuryl instead of benzyl chrysanthemates was examined. In the furan series, benzyl was an easily introduced and effective side chain. 5-Benzylfurfuryl chrysanthemate (III) showed promising activity against both house-flies

Ester interchange in the presence of sodium ethoxide was a more convenient procedure for making the *cis-trans*-chrysanthemate than use of chrysanthemoil chloride. Spectroscopic and analytical data fully substantiated the structures assigned.

## A Cyclobutane Derivative from Chloroprene Dimerization

KINETIC studies of the thermal polymerization of chloroprene indicate an unusual mechanism which involves formation of polymer from dimers and not from the chloroprene monomer<sup>1,2</sup>. The polymerization is initiated by traces of impurity in the monomer, and over a considerable range the observed rate and activation energy of polymer formation are identical with those for dimerization, indicating that the initial dimerization is the step which controls the rate in the consecutive reactions leading to polymer<sup>3</sup>. The characterization of the dimers and studies of the dimerization process are clearly prerequisites to understanding the mechanism of the polymerization. This communication is concerned with the initial problem of dimer separation and characterization.

It has been known for some time that chloroprene oligomerizes to form oils of low molecular weight<sup>4</sup>, and that six- and eight-membered cyclic dimers may be isolated from these products<sup>5-8</sup>. Possible Diels-Alder addition compounds are shown below (I-IV), and two isomeric dichlorocyclooctadienes can be proposed.

Brown *et al.*<sup>5</sup> showed that six- and eight-membered ring structures were present in the dimerization products from chloroprene, but did not characterize the individual isomers. Cope *et al.*<sup>7,8</sup> chemically identified the products of the dimerization at 80° as structure (III) and 1:6 dichlorocycloocta-1:5 diene, and structure (IV) was isolated as its dehydrochlorination product 1-chloro-4-vinyl-cyclohexa-1:3 diene. These results were supported by the more recent work of Nazarov *et al.*<sup>9</sup>, who in addition suggested that structure (I) is also present in dimers formed at 20° C and subsequently distilled at 90° C.

In our experiments the temperatures used in the preparation and separation of dimers have not exceeded 41° C. Products have been isolated from mixtures of two kinds, obtained as follows. (a) Chloroprene, which contained 1.0 per cent 1,1-diphenyl-2-picrylhydrazyl as a polymerization inhibitor, was allowed to dimerize at 35° C for 20 days, after which time the unreacted monomer was removed by high-vacuum pumping at -22° C. (b) Chloroprene, inhibited with 0.5 per cent *tert* butyl catechol, was allowed to dimerize at 38° C under gaseous nitric oxide for 20 days. The monomer was removed by distillation under reduced pressure of nitrogen. (We thank the Distillers Co., Ltd., for their co-operation in independently preparing this mixture.)

Fractionation of mixture (b) under reduced nitrogen pressure yielded two fractions, each of which accounted for about 25 per cent of the mixture. The remaining material consisted of residual monomer, high-boiling residues, and an intermediate fraction, shown by gas-liquid chromatography to be a mixture of the two main fractions. Elementary analysis of the two fractions gave results consistent with the empirical formula C<sub>4</sub>H<sub>5</sub>Cl (expected: C=54.25 per cent, H=5.65 per cent, Cl=40.10 per cent; found for fraction 1: C=54.45 per cent, H=5.59 per cent, Cl=39.23 per cent; found for fraction 2: C=53.02 per cent, H=5.38 per cent, Cl=39.70 per cent); and ebulliometric determinations<sup>10</sup> of the molecular weights in benzene solution indicated that the compounds were dimeric (molecular weight of fraction 1: 186 ± 5; molecular weight of fraction 2: 177 ± 5).

The boiling point of fraction 2 (40.0°-40.1° C, <1 mm), and its infra-red and nuclear magnetic resonance spectra, showed it to be a chlorovinyl chlorocyclohexene, as expected.

The infra-red spectrum of fraction 1 (boiling point 25.8-26.5° C, <1 mm) is shown in Fig. 1. The absorption bands at 3,090, 1,642, 1,417, 987 and 927 cm<sup>-1</sup> clearly indicate olefinic unsaturation, and the presence of only one sharp absorption band in the C=C stretching region suggests that the unsaturation is of a single type. Further, apart from the 927 cm<sup>-1</sup> band, the set falls directly within the ranges established for the vinyl group in hydrocarbon structures, and the assignment of the set to this group is supported by the absorption in the 1,855 cm<sup>-1</sup> region. The 927 cm<sup>-1</sup> band lies a little on the high side of the range usually quoted for vinylic out-of-plane C-H vibrations in hydrocarbons (915-905 cm<sup>-1</sup>), but this is not considered to be a serious objection to the interpretation in view of the established presence of chlorine. For the chlorine to have such an influence, it is necessary to assume that it is attached to a carbon α to the vinyl group. A striking feature of the spectrum is the absorption at 2,990 and 2,950 cm<sup>-1</sup>, which contrasts with the behaviour of fraction 2, and is considerably higher in frequency than that expected for C-H stretching vibrations in six-membered rings. It is in fact much more typical of smaller (strained) ring structure, and can be accommodated without any difficulty in the range established for methylene-group vibrations in cyclobutane. The only direct indication of impurity in the material is a band at 1,500 cm<sup>-1</sup>, which could be ascribed to traces of an aromatic component.

In the nuclear magnetic resonance spectrum (Fig. 2), the low-field bands are typical of the type-ABC spin system of a vinyl group not coupled to any other hydrogen nuclei. The upfield band is consistent with two pairs of mutually coupled (A<sub>2</sub>B<sub>2</sub>) cyclic methylenic protons. Integration of the spectrum shows the proton ratio to be three vinylic to two methylenic; that is, two vinyl groups per -CH<sub>2</sub>-CH<sub>2</sub>- fragment.

Taking both infra-red and nuclear magnetic resonance spectral evidence into account, the only feasible structure for fraction 1 is 1,2-dichloro 1,2-divinyl cyclobutane, a compound not hitherto suspected as a principal product of chloroprene dimerization.

The mixture obtained by procedure (a) was separated by thin-layer chromatography on a preparative scale.

Fig. 1. Infra-red spectrum of fraction 1.

Fig. 2. Nuclear magnetic resonance spectrum of fraction 1. Chemical shifts measured with respect to tetramethyl silane,  $\tau=10$ .

This was done at room temperature using *n*-hexane as eluent on silica gel 'HF254 (Merck)' plates. (The absorbent was coated to a thickness of 1.5–2 mm, and was then activated for 3 h at 120° C. A 2 mm band of 50 mg of the mixed dimers was coated on to the plate at 40° C. The separated bands were detected by two methods: (i) irradiation with 254 mμ ultra-violet light, and (ii) the development of an edge-strip with a 2 per cent solution of perchloric acid in methanol. The bands were scraped out and then soxhlet-extracted with ether.) Two bands were observed, and approximately the same weight of product was isolated from each. The products were spectroscopically characterized as identical with fractions 1 and 2 from preparation (b).

Thus 1,2-dichloro 1,2-divinylcyclobutane is one of the principal products of chloroprene dimerization at relatively low temperature. It is possible that the failure of other workers to isolate this compound may involve the higher temperatures previously used in the preparation or isolation of the dimers. At such temperatures the dichlorodivinyl cyclobutane might undergo a Cope rearrangement to form 1,6-dichloro 1,5-cyclooctadiene<sup>11</sup>. In the present work, a peak corresponding to this compound has been observed in high temperature gas chromatograms of dimer samples which have been shown spectroscopically to contain no 1,6-dichloro 1,5-cyclooctadiene before injection. This provides indirect evidence for the rearrangement.

We thank Dr. J. K. Brown and Dr. L. F. Thomas for their co-operation in the spectroscopic work and for invaluable discussions. We also thank I.C.I., Ltd. (Dyestuffs Division), for providing university study leave for P.A.L.

## IMMUNOLOGY

### Suppression of Antibody Production by Phytohaemagglutinin

THE *in vitro* effect of phytohaemagglutinin (PHA) on small lymphocytes from the peripheral blood is now well known<sup>1,2</sup>, and a limited number of studies of the effect of this substance *in vivo* have been made in man<sup>3,4</sup> and laboratory rodents<sup>5-7</sup>. Calne and his colleagues<sup>8</sup> reported the use of PHA to augment the immunosuppressive effect of 'Imuran'. We have studied the effect of PHA on the immune response of rats to foreign red blood cells, and the preliminary results of our experiments are reported here.

The animals used in these experiments were young Wistar albino rats of the same inbred strain weighing about 200–220 g. The PHA used was obtained from Burroughs Wellcome. The animals used were divided into several groups and were treated as follows:

**Group 1.** Three doses of 0.5 ml. PHA were injected intraperitoneally at 24 h intervals, followed 24 h later by 1 ml. of washed 1 per cent chicken erythrocyte suspension also injected intraperitoneally.

**Group 2.** These animals were given PHA as described but were not immunized with the erythrocytes.

**Group 3.** The animals in this group were not treated with PHA but were given an immunizing injection of chicken erythrocytes as in Group 1.

**Group 4.** These rats were immunized with erythrocytes as described but also received one injection of 0.5 ml. PHA 6 h later.

All animals were bled at the start of the experiment (day 0), immediately before immunization (day 3) and on the second, fourth and sixth days after immunization (that is, days 5, 7 and 9). The treated rats in Groups 1 and 2 were also bled daily during the administration of the PHA.

Complement dependent haemolytic antibodies were detected by adding 2 per cent washed chicken erythrocytes to doubling dilutions of test sera in the presence of excess complement. The serum-erythrocyte-complement mixtures were incubated at 37° C for 60 min and then examined for haemolysis. 50 per cent lysis was taken as the end point of antibody activity.

Results of a typical experiment are summarized in Table 1; other experiments have given similar results.

Table 1. HAEMOLYSIN PRODUCTION IN RATS WITH AND WITHOUT PHA TREATMENT

Day	Group 1	Group 2	Group 3	Group 4
0	—	—	—	—
1	—	—	—	—
2	—	—	—	—
3*	2	2	2	—
5	—	—	—	—
7	—	—	16; 128; 64;	32; 8; 128;
			64; 64	64; 256
9	2; 4; —	32; 8	128; 64; 128;	256; 1,024; 256;
			128; 64	512; 1,024

Antibody production is expressed as the reciprocal of the highest dilution giving 50 per cent lysis of chicken erythrocytes.

\* Immunization after the sample was taken.

Haemolytic antibody was found in low titre in a number of Group 1 animals before immunization. No activity was found on either the second or fourth day after immunization in Group 1 animals, but low titre antibody was found in most 2 days later.

In Group 2 animals also, little haemolytic antibody activity was found with the exception of low titre in one animal on the seventh and ninth days of the experiment.

Naturally occurring haemolytic antibody was not found in pre-immunization samples from Group 3 rats. No antibody was detected until the fourth day after immunization, when considerable titres were obtained in all animals, persisting until at least the sixth day after immunization.

As in Group 3, no haemolytic antibody was detectable in Group 4 until the fourth day after immunization.

Fairly high titres were recorded in most animals on the fourth day, and on day six the titres were higher than those found in any other group in this experimental series.

Similar clear-cut results of antibody production were found using a haemagglutination technique, although in our hands it appeared to be less sensitive than the test using complement.

From these results it is readily apparent that parenteral administration of PHA before immunization with chicken erythrocytes considerably suppresses humoral antibody formation. On the other hand, PHA given 6 h after the antigen is not followed by immune suppression but seems, from our limited data, to enhance the production of antibody. Experiments are being undertaken to determine whether or not similar results are obtained when rats are given more vigorous post-immunization treatment with PHA. There is some evidence from these results and previous experiments carried out by us that the administration of PHA can elicit the production of naturally occurring antibody. This point is being investigated further.

Other experiments which we have carried out in which tetanus toxoid was given before immunization showed no suppressive effect on anti-chick erythrocyte antibody production. This suggests that PHA did not act by a mechanism involving antigenic competition.

In view of the fact that PHA transforms small lymphocytes of peripheral blood and thoracic duct to large blast-like cells *in vitro* it seems not unreasonable to suppose that a similar transformation of immunologically competent cells occurs *in vivo* with the "siphoning off" of such cells so that they are not available to react with the immunizing antigen. A possible site for such a transformation may be the germinal centres of the lymphoid tissues. It has been shown that the spleens of rats receiving intraperitoneal injections of PHA have larger numbers of germinal centres which are also larger in size than in control rats<sup>7</sup>.

Thus PHA may become of value as an immunosuppressive drug. It is apparently harmless in man in doses so far used<sup>3,4</sup>. It may give rise to untoward side effects in animals if used in high doses<sup>5</sup>. We noticed that a number of rats treated with PHA tended to be less active than those left untreated and sometimes assumed a hunched posture. This apparent lack of toxicity is in contrast to the marked side effects which may be brought about by other immunosuppressive agents such as X-irradiation and cytotoxic drugs. It may therefore be of some value in the field of organ transplantation. Our preliminary observations of the enhancement of antibody production brought about by PHA administered after the antigen suggest that it would be ineffective, or possibly deleterious, if used to treat auto-immune diseases such as haemolytic anaemia. Its use in such a context might result in an enhancement of the disease process. The effect of PHA as an immunosuppressive drug in transplantation immunity has yet to be critically assessed.

## Immune Response to Substituted Arsanil-azo-Human Gamma Globulin Conjugates in Mice Tolerant to Human Gamma Globulin

I HAVE recently investigated the immune response to a variety of azo-human gamma globulin derivatives in mice tolerant to the carrier protein, human gamma globulin (HGG)<sup>1</sup>. Judged by the elimination of trace-labelled HGG, it seemed that a single injection of azo-protein in Freund incomplete adjuvant had only a marginal effect on tolerance. Two exceptions were noticed, however, in experiments where mice tolerant to HGG were challenged with either double substituted azo-HGG or with *o*-sulphanil-azo-HGG. On the other hand, compared with controls challenged with HGG, two injections of azo-HGG, 4-5 weeks apart, usually caused a significant increase in the number of responsive mice. Gel-diffusion techniques revealed that the injection of azo-proteins did not regularly cause a full return to responsiveness to HGG in mice neonatally rendered tolerant to this protein. The specificity of the antibody formed was found to be directed against antigenic determinants comprising the haptenic group and part of the protein carrier. The altered HGG preparations used had 2.6-13.6 azo groups per molecule of HGG and cross-reacted to 80-100 per cent with native HGG. The following experiments were devised to investigate the effect of azo-HGG with more haptenic groups attached and cross-reacting to a lower extent than the preparations previously used.

Diazonium salt of *p*-amino benzenearsonic (arsanilic) acid (*p*-A) was coupled with HGG as described earlier<sup>1</sup>, except that the molar ratios of diazotized arsanilic acid to HGG were greater by factors of 2 and 4. Furthermore, conjugates were prepared at pH 7.5 and pH 9.5, respectively, by simultaneous addition of 0.2 normal sodium hydroxide. (Other than the pH conditions of preparation these conjugates were identical.) After completion of the reaction the mixtures were kept for 12 h at 0° C and were then extensively dialysed against distilled water for several days and lyophilized. The analytical data are shown in Table 1. For the sake of comparison, a preparation similar to the *p*-A-HGG used in the previous investigation is presented in the first column. It can be seen that when the amount of diazonium salt added to the reaction mixture was increased by a factor of 2 and 4, the number of azo groups determined in the conjugates increased by a factor of about 1.5-3, whereas the content of arsenic rose by a factor of about 2-4. The ratio of arsenic groups to azo groups was found to be 2.87-4.4, which indicates that a substantial amount of arsanilic acid had been coupled to the protein by linkages other than —N=N—. The pH of the reaction mixture did not influence the total amount of azo groups, but in all conjugates prepared at pH 9.5 the amount of arsenic was higher than in those made at pH 7.5. The extent of cross-reaction determined by quantitative precipitation using a rabbit anti-HGG serum<sup>1</sup> is shown in the eighth column. Unfortunately, preparations *B* and *C* were insoluble; however, data on the degree of substitution found in previous experiments and obtained with preparations *D* and *E* suggest that cross-reaction of *B* and *C* with native HGG must be intermediate—probably between 80 and 100 per cent.

Tolerance was induced in neonatal *C57BL* mice by injecting 20 mg HGG within 24 h of birth<sup>2</sup>. The techniques used in the immunization, the challenge procedure, and the tests for tolerance were the same as those described earlier. Briefly, mice were injected at various intervals after birth with 0.1 mg HGG or *p*-A-HGG in 0.05 ml. of incomplete Freund adjuvant, distributed among three foot-pads<sup>3</sup>. Antibody formation was determined by following the elimination of trace-labelled antigen<sup>4</sup> and the tolerance was evaluated graphically according to the pattern of elimination<sup>2,5</sup>.

The results obtained after a single injection of *p*-A-HGG at an age of 7-9 weeks are shown in the last column.

Table 1. ANALYSIS AND DEGREE OF CROSS-REACTION OF VARIOUS *p*-A-HGG PREPARATIONS AND THE EFFECT OF ONE INJECTION AT THE AGE OF 7-9 WEEKS ON TOLERANCE TO HGG

Preparation	Diazotized arsanilic acid added (moles)	pH	-N=N-/HGG	As/HGG	Arsenic (per cent)	As/-N=N-	Cross-reaction with native HGG (per cent)	Responding mice (per cent)†
A	115	7.5	10.1	29.0	1.36	2.87	98	55
B	230	7.5	14.2	51.0	2.39	3.50	ND*	60
C	230	9.5	15.5	67.0	3.14	4.32	ND*	7
D	460	7.5	27.4	85.8	4.02	3.13	37	42
E	460	9.5	27-30	120.0	5.62	4.0-4.4	37	14

\* Not done: B and C were insoluble.

† Challenged with *p*-A-HGG. Twenty-five per cent of the control group, challenged with HGG, showed a low degree of responsiveness. The average size of the groups was seventeen mice.

At this time, 25 per cent of the controls, challenged with HGG, already showed a low degree of responsiveness, as judged by a somewhat faster elimination rate of the tracer as compared with a second control which had neither been in contact with HGG after birth nor had been injected with HGG in adjuvant (elimination control). On the other hand, 55, 60 and 42 per cent of the mice challenged with *p*-A-HGG, A, B and D, respectively, showed a low degree of responsiveness. The responsiveness, however, was only partial. In no instance did any mouse reveal an immune elimination of the tracer as did mice which had been injected after birth with *p*-A-HGG or HGG in adjuvant (immunization control) instead of soluble HGG. In contrast to these findings are the results obtained with the preparations C and E. In both groups, fewer animals than in the controls were responsive. This may reflect certain chemical properties (that is, high arsenic content) inherent in these conjugates prepared at pH 9.5.

The degree of cross-reaction of azo-protein conjugates with native HGG did not seem to correlate with their ability to "break" immunological unresponsiveness to the carrier protein<sup>1</sup>. This view is clearly demonstrated by the present findings. Preparations A and D had similar effects on the tolerance to HGG, although they cross-reacted to 98 and 37 per cent, respectively. The conjugates D and E, which cross-reacted to the same extent, clearly acted differently. It is concluded that it is not the degree of 'foreignness' to the tolerogen but rather the chemical nature of a hapten-protein conjugate which is of prime importance for the termination of tolerance to the carrier protein.

### Identification of an Antigenic Determinant [of Collagen treated with Hydroxylamine]

THE treatment of collagen with hydroxylamine, which splits ester-like bonds, produces subunits carrying newly formed aspartic acid hydroxamates<sup>1,2</sup>. Their alcohol counterparts are not yet fully identified. A series of investigations on the immunogenicity and specificity of collagen<sup>3,4</sup> showed that collagen treated with hydroxylamine (HC) is an antigen which induces the formation of two types of immune sera: type 1 containing only antibodies against the area of hydroxylamine treatment (HC-antibodies); type 2 containing additionally antibodies against the general collagen structure. HC therefore acts when used for immunization like a conjugated protein. Investigation of haemagglutination inhibition showed that early sera were predominantly of type 2. Hyperimmune sera, however, were mostly of type 1. Inhibition experiments proved that sera with only HC-antibodies (type 1 immune sera) can be inhibited by HC, but are not inhibited by collagen preparations such as parent gelatine. Antisera which possess both anti-

bodies (type 2 immune sera) are inhibited extensively by HC and to a lesser degree by parent gelatine. Additionally, inhibition experiments were carried out with peptides obtained from HC, acid-soluble collagen and insoluble collagen by treatment with trypsin or collagenase<sup>5</sup>. Only peptides obtained from HC inhibited HC-antibodies and these peptides when used in sufficient amounts caused a complete inhibition of potent antisera.

The experiments described here were designed to obtain further information about the antigenic determinants of HC. Antisera were obtained in rabbits by immunization with HC from calf joint collagen (No. 49, 51, 82, 186), with HC from rabbit skin collagen (No. 56) and with parent gelatine from calf skin collagen (No. 181). The preparation of HC used for coating red cells and used as inhibitor was obtained from calf skin collagen. Haemagglutination and haemagglutination-inhibition were carried out as previously described<sup>3,4</sup>. Further inhibitors were amino-acid hydroxamates and amino-acids.

Two serological systems were selected for the inhibition experiments. HC served in both as coating antigen on red cells. These red cells were either agglutinated by type 1 immune sera, containing only HC-antibodies, or by anti-parent gelatine sera which served as controls. The anti-parent gelatine antibodies react only with the collagen structure of HC and do not detect the specificities caused by hydroxylamine treatment.

Table 1. INHIBITORY ACTIVITY OF HC, AMINO-ACID HYDROXAMATES AND AMINO-ACIDS IN PASSIVE HAEMAGGLUTINATION OF ANTI-HC AND ANTI-PARENT GELATINE SERA WITH HC-COATED CELLS

Inhibitor	Concentration (μg/0.05 ml.)	Reciprocal titre of serological systems HC/anti-HC	HC/anti-parent gelatine
Saline	—	128	64
Hydroxylamine-treated collagen	0.0025	<2	<2
DL-Aspartic acid hydroxamate	0.25	<2	64
" " "	0.025	2	64
" " "	0.0025	16	64
α-Alanine hydroxamate	0.25	32	64
β-Alanine hydroxamate	0.25	64	64
Glycine hydroxamate	0.25	32	64
Aspartic acid	0.25	64	64
Asparagine	0.25	64	64
Glycine	0.25	128	64

Table 1 shows the results of inhibition experiments; 0.05 ml. of HC-preparation, amino-acid hydroxamates and amino-acids in concentrations as indicated were added to 0.05 ml. each of geometrically progressing dilutions of antiserum. Red cells coated with HC were later added. Titre controls were carried out by using 0.05 ml. of saline instead of inhibitor. The extent of titre decrease indicated the inhibiting activity. Investigations in the HC/anti-HC system showed that HC was a strong inhibitor. DL-Aspartic acid hydroxamate also showed significant inhibition which depended on the concentration used. Hydroxamates of the other amino-acids and the parent amino-acids caused little or no inhibition. In investigations in the HC/anti-parent gelatine system (control) HC inhibited because of its collagen property. DL-Aspartic acid hydroxamate as well as the other compounds were inactive.

The minimum inhibiting doses of HC and different amino-acid hydroxamates were determined by the technique of Springer and Williamson<sup>6</sup>. Five different type 1 immune sera (HC-antibodies) were diluted to a titre of 1:8 (8 agglutinating units). Equal volumes of serum and

inhibitor in different concentrations were incubated for 10 min at 23° C before addition of red cells coated with HC. The minimum amounts of inhibitor which prevented the antisera from agglutinating the cells are recorded in Table 2.

Table 2. MINIMUM AMOUNTS (MG/ML.) OF COLLAGEN TREATED WITH HYDROXYLAMINE AND AMINO-ACID HYDROXAMATES GIVING COMPLETE HAEMAGGLUTINATION-INHIBITION OF EIGHT MINIMUM AGGLUTINATING DOSES OF ANTI-HC SERUM

Inhibitor	Anti-HC sera used				
	No. 49	No. 51	No. 56	No. 82	No. 186
Hydroxylamine-treated collagen	0.0012	0.0012	0.0012	0.0025	0.0012
DL-Aspartic acid hydroxamate	0.04	0.08	0.08	0.16	0.02
$\alpha$ -Alanine hydroxamate	>5	>5	5	>5	5
$\beta$ -Alanine hydroxamate	>5	>5	>5	>5	>5
Glycine hydroxamate	>5	>5	5	>5	>5

$\alpha$ - and  $\beta$ -Alanine hydroxamate and glycine hydroxamate showed little or no activity at the highest concentration used. Between the minimum inhibiting amounts of HC and DL-aspartic acid hydroxamate a weight ratio of 1:16 to 1:66 was observed. For determination of the molar ratio, the number of hydroxamate groups in the HC molecule (6 moles/1,000 moles of amino-acids<sup>2,7</sup>) has to be considered. The calculation according to the respective molecular weights leads to a factor of approximately one hundred. The molar ratio between HC and DL-aspartic acid hydroxamate is therefore in the order of 1:2,000 to 1:6,000. Similar ratios were observed in typical azo-hapten systems<sup>8</sup>. The high ratio makes it likely that the combining site of HC-antibodies is directed against an area larger than that of aspartic acid hydroxamate alone. Probably one or more adjacent amino-acids are also involved.

The investigations performed showed that aspartic acid hydroxamate has a specific activity in the HC/anti-HC system in contrast to all other amino-acid hydroxamates and amino-acids tested. Aspartic acid hydroxamate can be considered at least as one of the antigenic determinants of collagen treated with hydroxylamine.

### Immunological Tolerance induced by Cyclophosphamide assayed by Plaque Spleen Cell Method

SINCE the demonstration in the rabbit of specific immunological tolerance when 6-mercaptopurine was administered together with the antigen bovine serum albumin<sup>1</sup>, numerous examples of tolerance induced by immunosuppressive drugs have been demonstrated<sup>2</sup>. This phenomenon of drug-induced tolerance is a particularly favourable system for the analysis of the fundamental and still incompletely understood problem of specific immunological unreactivity, but so far it has received little attention in this connexion.

The present communication is our first report on the analysis of immunological tolerance induced with the alkylating agent cyclophosphamide<sup>3</sup>. We have chosen the antigen sheep cells because the newly described technique of Jerne<sup>4,5</sup> allows the determination of the cellular kinetics of developing tolerance. In this system we have observed that the cells of the unstimulated mouse spleen which produce 19S sheep cell haemolysin disappear after

injection of cyclophosphamide only when antigen (sheep cells) is administered concurrently, that is in the same condition of antigen administration which is necessary for the induction of tolerance.

A satisfactory system employing sheep cells as the antigenic stimulus for the evaluation of immunosuppressive drugs in mice has been described<sup>6</sup>. We have obtained complete and lasting (longer than 2 months) specific immunological tolerance after a single intravenous injection of 0.8 ml. of a 30 per cent sheep cell suspension ( $6 \times 10^8$  cells) when four intraperitoneal injections of cyclophosphamide (each dose 85 mg/kg) are given daily beginning on the day of antigen administration. Complete tolerance is regularly obtained in CBA mice without significant mortality and can be maintained by weekly intraperitoneal injections of sheep cells. Analysis of this system by means of Jerne's technique for determining the number of anti-sheep cell antibody-producing cells in mouse spleen is presented in Fig. 1. In these experiments each point represents the arithmetic mean of six individual mouse spleens, each of which was plated on a single 100 mm  $\times$  15 mm disposable 'Falcon' Petri dish. Each spleen was separately sieved with a 'Cyto-sieve', and the cells were counted and then concentrated by centrifugation into 0.2 ml. of Gey's balanced salt solution. Agarose solution (0.5 ml., 2.5 per cent) was added to 1.5 ml. of Gey's heated to 47° C, and to this were added the spleen cell suspension and 0.1 ml. of 20 per cent sheep cells, both at 37° C. After mixing, this cell suspension was poured into the Petri dish which contained a sublayer of 10 ml. of 1.2 per cent agarose. When the agarose had gelled, the dish was incubated at 37° C for 2 h, complement was added (1 ml. of a 1:10 dilution of lyophilized guinea-pig serum), and the plate was incubated for an additional hour. The haemolytic plaques surrounding each antibody-producing

Fig. 1. The response of total spleen cells and 19S haemolysin-forming spleen cells to cyclophosphamide and cyclophosphamide plus sheep cell administration. —○—○, Control; —▼—▼, cyclophosphamide; —●—●, cyclophosphamide plus sheep cells.

cell were counted with the aid of a bacteria colony counter. Other details are similar to those of the original publication<sup>4,5</sup>.

The upper part of Fig. 1 shows the total spleen cell count in control animals, and at various times after the administration of *cyclophosphamide* both with and without antigen (sheep cells). In the middle part of Fig. 1 the total number of haemolytic plaques (antibody-forming cells) are graphed, and in the lower portion the number of plaques/million spleen cells is presented. The total spleen cell count drops sharply after the injections of *cyclophosphamide*, reaching a minimum on about the seventh experimental day and returning rapidly to normal by the seventeenth day. Of most interest is the effect of these regimens on the number of haemolysin-producing cells (19S plaques) of the spleen. Thus, the untreated CBA mouse spleen contains an average of forty to sixty cells producing antibodies to sheep cells. After administration of *cyclophosphamide* alone the fall and subsequent return of haemolysin-producing cells closely parallel these alterations of total spleen cell count. This parallel is illustrated in the lower part of Fig. 1 where it is seen that the number of plaques/million spleen cells remains constant throughout the period of observation. When sheep cells are administered at the time of the first dose of the drug the results are strikingly different; there is now a selective disappearance of the anti-sheep cell antibody-producing spleen cells which is complete by the tenth experimental day. On the seventeenth day there is an average of one plaque in two spleens (0,0,0,0,3,0 in the spleens examined) in these animals. Furthermore, as the spleen of the animal treated with sheep cells and *cyclophosphamide* is repopulated, there is no restoration of haemolysin-producing cells. The lower portion of the figure calls attention to the precipitous and permanent fall of 19S plaques in these antigen-treated animals when expressed for each million spleen cells.

It seems likely that the antigen-dependent disappearance of haemolysin-producing cells observed during tolerance induced by *cyclophosphamide* is related to the specific unresponsiveness produced. (Administration of ox cells or rabbit cells together with *cyclophosphamide* produced neither tolerance to sheep cells nor the disappearance of sheep cell haemolysin-producing plaques.) The present work, therefore, supports a clonal selection theory of antibody synthesis<sup>7-9</sup> and the additional supposition that the 19S cells observed in the unstimulated spleen are related to the cells which respond to the sheep cell antigen. A falling quotient of 19S haemolysin-producing cells to total spleen cells may prove to be a very early indication of developing tolerance.

It must be recognized that the experimental evidence connecting the 19S haemolysin-producing cell of the unstimulated spleen with that cell observed after antigen stimulation is circumstantial. Experiments which used a technique of *in vivo* cloning<sup>10</sup> suggest that the number of cells responsive to sheep cells in the normal mouse spleen is about 5,000 rather than 50-100 as indicated by the Jerne technique<sup>4</sup>. A plausible solution to this dilemma is that the Jerne technique detects a cell which is related to, or derived from, or is a selected part of the antigen-responsive clone rather than the clone itself. The present experiments are none the less additional evidence relating the 19S cell of the resting spleen to the antigen-responsive clone.

Two explanations have been put forward for drug-induced immunological tolerance<sup>2,11,12</sup>. The first proposes that these compounds act in conjunction with antigen to turn off the immune mechanism by blocking the transcription of information somewhere within the receptor or effector lymphoid cell; essentially, a ribonucleic acid mechanism is implied. Alternatively, it has been proposed that antigen renders these cells selectively susceptible to the cytotoxic effects of the immunosuppressive drugs, essentially a deoxyribonucleic acid mechanism.

Our experiments do not distinguish with certainty which of the two possible mechanisms is responsible for the antigen-dependent, drug-induced disappearance of 19S plaques. It seems plausible, however, that the metabolic alterations preparatory to cell division render the antigen-stimulated, haemolysin-producing cells particularly susceptible to *cyclophosphamide*. In view of the massive cell destruction which occurs throughout the spleen simultaneously and the known cytotoxic effects of *cyclophosphamide*<sup>13</sup>, enhanced destruction of these stimulated cells is an attractive explanation of the immunosuppressive and tolerance production of the drug. There is convincing evidence that *cyclophosphamide*, along with other alkylating agents, has its primary effect on deoxyribonucleic acid<sup>14</sup>, replication of which is necessary for mitosis.

*Cyclophosphamide* (administered as a single dose) however, will induce complete tolerance to sheep cells when given up to three days before the injection of antigen. Thus, the somewhat unlikely assumption must be made that enhanced susceptibility to antigen-stimulated cell death persists for 72 h after administration of *cyclophosphamide*.

The present experiments do not exclude the possibility that 19S-producing cells, rather than being destroyed, are converted to cells which no longer produce 19S antibody. We have examined directly the possibility of conversion to 7S-producers by employing the techniques of Dresser and Wortis<sup>15</sup> and Sterzl and Riha<sup>16</sup> which utilize a rabbit anti-mouse  $\gamma$ -globulin serum to detect 7S antibody-forming cells. No 7S haemolysin-producing cells were detected 5 days after treatment with *cyclophosphamide* and sheep cells. (The plates were incubated for an additional hour with 2 ml. of a 1:50 dilution of rabbit antiserum before complement addition<sup>15</sup>). It remains possible, however, that 19S cells have been converted to cells which do not produce antibody. This alternative does not reduce the likelihood that the antigen-dependent 19S plaque disappearance is closely related to immunological tolerance induced by the drug.

We thank Dr. John H. Humphrey of the National Institute for Medical Research for advice. The work was supported by a research grant from the U.S. Public Health Service.

### Synergistic Action of Antibodies: Detection of Circulating Antileucocyte Antibodies after Skin Transplantation

LEUCOCYTE isoantibodies, which appear after skin homo-transplantation in rabbits and rats, cannot usually be detected by simple agglutination. This report describes a

method for demonstrating these isoantibodies, which is based on the synergistic action of two antibody systems<sup>1,2</sup>, and which is also suitable for leucocyte typing. In this method donor leucocytes are agglutinated by the joint action of two different antibodies, each used in a subagglutinating titre.

Local wild strain rabbits and albino rats were used. Full thickness skin homografts, 2 cm × 1 cm, were performed in rabbits on the inner surfaces of both ears, without the use of sutures<sup>3</sup>. In rats, one full thickness transplant, 3 cm × 2 cm, was sutured on the back, and covered by a gauze pressure bandage for 5 days. The grafts were inspected daily and the progress of rejection was noted. Blood was collected from graft recipients by cardiac puncture, both at the time of rejection and later. Sera were inactivated, and stored at -20° C until testing.

Anti-rabbit and anti-rat-leucocyte sera were prepared by immunization of hens with washed suspensions of rabbit and rat leucocytes respectively, and these were injected intravenously and subcutaneously with complete Freund's adjuvant. The sera were absorbed with washed erythrocytes, free of leucocytes. Any weak antiglobulin activity was neutralized by the addition of normal rabbit or rat serum. The sera were titrated with rat and rabbit leucocytes, respectively, and dilutions giving a very weak positive reaction (a few leucocyte clumps of two to four cells) were used. Leucocytes were separated from the donor of the skin graft by differential sedimentation, as described previously<sup>4</sup>. A suspension of about 30,000-60,000 cells/cm<sup>2</sup> was prepared.

The test was performed in siliconized glassware by addition of one drop of the leucocyte suspension to 0.2 ml. of the recipient's serum, in a series of double dilutions. The tubes were incubated for 30 min at room temperature. After centrifugation at 3,000 r.p.m. for 15 sec the serum was removed and 0.2 ml. of the serum containing hen anti-rabbit or hen anti-rat antibodies was added. Results were read microscopically after further incubation for 30 min at room temperature, and centrifugation at 3,000 r.p.m. for 15 sec.

Additional tests were carried out with leucocytes of animals chosen at random and the graft recipient's own leucocytes as well as normal sera were used instead of the graft recipient's sera. The test was performed repeatedly on twenty-one rabbits and twenty-six rats. The same pattern of results was observed both in homografted rabbits and rats, although titres were slightly lower in rats. Typical results are given in Table 1.

Very weakly positive, or negative, results were obtained whenever the heteroantibodies were incubated with the donor's white blood cells first and the isoantibodies were added later. Positive results were also found with leucocytes of some random animals, as shown in Table 2.

The test based on the synergistic action of subagglutinating quantities of iso- and hetero-antileucocyte antibodies

was found to be a simple and reliable serological method for the detection of post-homograft humoral antibodies.

The antibodies formed during skin rejection and which react with donor's leucocytes are probably antibodies elicited by histocompatibility antigens. The cross-reactivity observed between the donor and random leucocytes suggests the presence of at least one histocompatibility antigen common to the skin donor and the random animal. This method is at present being used for the detection of common histocompatibility antigens and, in consequence, for tissue typing.

### Species Specific and Cross-protective Functional Antigens of the Tapeworm Embryo

EVIDENCE<sup>1</sup> has been reported which supports the hypothesis that at least two immune responses may occur to larval taeniid tapeworms in the intermediate host, and that both responses can be elicited by a single parenteral injection of homologous viable eggs or activated embryos. The initial response appears to prevent the establishment of the challenge infection at the site of election, possibly by preventing the invading embryo from penetrating the intestinal barrier. The later response occurs at the site of election against the growing metacystode.

Further data<sup>2</sup> showed that part of the functional antigen complex is shared by the embryos of two species of the same genus parasitizing the same host. These two species are *Taenia hydatigena* and *T. ovis*. The evidence for a shared functional antigen between these two sheep metacystodes and the rabbit metacystode *T. pisiformis* was less certain.

The question was raised whether or not embryos of different genera also share part of this functional antigenic complex. To determine this, a trial, involving four groups each of twenty sheep free of worms (*Strongyloides* spp. excepted), has been carried out. Half the lambs in each group were vaccinated by the intramuscular route with the viable eggs and half with the activated embryos of *Echinococcus granulosus*, *T. hydatigena*, *T. ovis* and *T. pisiformis*. These lambs together with ten control animals were challenged 94 days later with 2,500 eggs of *E. granulosus*. About 30 months later, these animals were autopsied.

The activated embryos antigen complex for each species was prepared by immersing eggs expressed from gravid proglottids in Silverman hatching solution<sup>3</sup>. The viable egg antigen consisted of untreated eggs. The dose rate of antigen was 1,000-50,000 eggs or embryos for each species.

Table 1 summarizes the results. The range of hydatid cysts established and surviving is given for each treatment. The number of cysts was by no means normally distributed, thus the transformation  $y = \log(1 + x)$  has been used to "normalize" the distribution, so that significance tests would be valid. These data show that when sheep were vaccinated with the eggs of each of the sheep metacystodes, only the eggs of the homologous species induced significant protection against hydatid

Table 1

Recipient's serum, rabbit	Agglutination titre with donor's leucocytes
Before grafting	—
10 days after grafting	—
12 days after grafting	1/8

\* Surviving for 30 months.

† Mean and standard deviation obtained from transformed figures  $y = \log(1+x)$ .

‡ Resistance indices calculated from the following:

$$\text{Resistance to the establishment of } E. \text{ granulosus is } 1 - \left[ \frac{Nt + Vt}{Nc + Vc} \right] \times 100$$

$$\text{Resistance to the survival of } E. \text{ granulosus is } \left[ \frac{NtVc - NcVt}{Vc(Nt + Vt)} \right] \times 100$$

§ Significant at 1 per cent level.

$Nt$  is the number of necrotic cysts per animal within each test group;  $Nc$  is the number of necrotic cysts per animal within each control group;  $Vt$  is the number of viable cysts per animal within each test group;  $Vc$  is the number of viable cysts per animal within each control group.

cysts. When sheep were immunized with the activated embryos, however, resistance was also induced to the challenge infection by the embryos of some of the heterologous species.

This evidence suggests that there are at least two functional antigen complexes. One is species specific, and is present in the eggs of the homologous species; the other is present in the activated embryos but not the eggs of the heterologous species. The former exerts an effect against both the establishment and the survival of the challenge organism, but the latter induces resistance only to the growing larval form at the site of election.

Although it is possible that the appropriate immunogen is not produced in sufficient amounts in the abnormal host, the previously recorded<sup>2</sup> and present evidence for a shared antigen between the sheep metacestodes and the rabbit metacestode *T. pisiformis* suggests that not all species within the same or different genera have a common functional antigen.

## MICROBIOLOGY

### Isotope Effects on the Morphology of Fully Deuterated Bacteriophage $T_2$

CONSIDERABLE changes in the isotopic composition of living organisms may result in gross changes in the structure of cells and organelles<sup>1</sup>. The morphological changes attendant on isotopic substitution have a special interest, because the isotopically altered organisms are viable and biologically competent; and, as a consequence, correlations between structure and function become possible. Thus, for example, the chloroplasts of fully deuterated green algae<sup>2</sup> are observed under the electron microscope to be markedly different from those of the prototype organism although the deuterated algae are fully capable of photosynthesis. Because deuterated bacteriophage have been found useful in genetic<sup>3</sup> and biochemical<sup>4</sup> investigations, we have now fully examined deuterated phage by electron microscopy to determine the morphological consequences of deuteration on a virus.

*Escherichia coli* B (A.T.C.C. No. 11303) and bacteriophage *E. coli*  $T_2$  (A.T.C.C. No. 11303- $T_2$ ) were used. The bacteria were grown in aerated broth and, while the cul-

tures were in their logarithmic growth phase, they were inoculated with about 0.2 ml. of phage suspension. Aeration was continued for 24 h. Then the infective phage in the culture were assayed according to the double layer technique of Adams<sup>5</sup>. The Petri dishes containing twenty or fewer plaques were used for donor plaques. Phage from a single donor plaque were inoculated into two parallel *E. coli* cultures, one containing deuterated broth<sup>6</sup>, the other broth of normal isotopic composition. Incubation of the ordinary cultures was continued for 24 h, while the deuterated cultures were incubated for 7 days. Then the ordinary cultures were refrigerated for 1 week, while the deuterated cultures were refrigerated for 2-4 weeks. The longer the cultures were held within these periods, the greater the number of phage particles that could be collected. Concentration of the phage was achieved by centrifuging the cultures at 5,000g for 15 min, followed by centrifugation at 35,000-170,000g for 1-4 h. The higher forces and longer periods were used to concentrate the deuterated phage.

The samples were prepared for electron microscopy by negative staining with sodium or potassium phosphotungstate<sup>7</sup> in water and deuterium oxide at pH's (or pD's) in the range of 6-8. Just before staining, each sample was assayed for virulence, and only infective samples were examined electron microscopically.

Table 1. APPROXIMATE DIMENSIONS OF ORDINARY AND DEUTERATED BACTERIOPHAGE  $T_2$  (m $\mu$ )

	Head length	Head width	Tail length*	Tail width
Ordinary	9.9	7.1	10.2	1.6
Deuterated	11.0	8.9	11.4	2.64

\* Indicates distance from head to, but not including, the tail fibres. The neck above the sheath and the plate are included.

Deuterated  $T_2$  bacteriophage are larger than phage grown under normal conditions (Table 1). Besides the size difference, there is a difference in shape. The deuterated phage appear to have more bulbous heads than their normal counterparts. The sides of normal phage heads seem to be approximately flat planes, whereas those of deuterated phage seem to bulge. The tail fibres of deuterated phage are shorter than those of their normal counterparts. Frequently, in deuterated phage, these fibres are not seen at all or are anomalous (Fig. 1). High resolution electron micrographs suggest that there is a difference in the structure, or at least in the arrangement, of the subunits (capsomeres) of the phage tail. Micrographs taken at moderately high resolution show that two kinds of striations can be seen in the tails of bacteriophages. One variety of striation suggests a shallow pitched helix. The other type of striation exhibits a far steeper pitched helix. The second kind of striation is observed in both deuterated and normal forms. (It was not investigated carefully and we shall only suggest that it is the wrapped-up tail

fibres.) When the wrapped-up tail fibres are not present, the normal phage tail shows the shallow pitched striations; on the other hand, the deuterated phage tail has a lumpy appearance. At highest resolutions, the tail of normal phage appears to contain, and to consist largely of, spheroid bodies arranged in linear order. Fig. 1 shows some of these bodies arranged at nearly a right angle to the long axis of the tail in the hydrogen phage, but some other micrographs indicate that there is a helical arrangement of the sub-units. Deuterated virus also show tail sub-units, but linear arrangement is seldom observed. Instead, the capsomeres, which appear to be somewhat larger than those in ordinary virus, seem to be irregularly distributed.

Fig. 1. *E. coli* T<sub>2</sub> bacteriophage grown under normal (a) and deuterated (b) conditions.

That mere immersion in deuterium oxide is not sufficient to produce the observed differences is indicated by the fact that viruses maintained the morphology typical of their culture type regardless of whether staining solutions were made up in water or deuterium oxide. For the present, we are inclined to the view that the peculiarities result from the size and location of the protein sub-units. The disordered arrangement of these sub-units in the deuterated virus could account not only for the extraordinary morphology of the phage but also for the reduced infectivity observed in these and in partially deuterated phage<sup>8</sup>. Such disordered protein sub-units might also contribute to the reduced morphological order seen in all deuterated micro-organisms that have so far been described.

This work was performed under the auspices of the U.S. Atomic Energy Commission. Early phases of the work

### Viruses of the Lymphogranuloma- Psittacosis Group isolated from Opossums: Opossum Virus B

EARLIER I reported<sup>1</sup> the isolation from opossums of two distinct new disease agents belonging to the lymphogranuloma-psittacosis group (PLGV), designated them opossum viruses A and B, and described studies with opossum virus A (OVA). This communication reports investigations with opossum virus B (OVB), by the same procedures used with OVA.

OVB was isolated from a brown masked opossum (*Metachirus nudicaudatus*)<sup>2</sup>. This opossum was killed when it was found to be in respiratory distress twenty days after its arrival at the Carlos Finlay Institute in Bogota, Colombia, from the place near Villavicencio where it had been trapped<sup>3</sup>. Autopsy revealed pulmonary consolidation.

A suspension of lung tissue from the opossum was injected intracerebrally, intraperitoneally and intranasally into mice. Those inoculated by the intracerebral and intraperitoneal routes remained well, but those receiving the agent intranasally developed signs of respiratory illness in 2-6 days, depending on the OVB concentration in the inoculum, and died. Elementary bodies characteristic of the PLGV group of viruses were demonstrated in impression smears of lung tissue stained according to Macchiavello's method. Yolk sac suspensions from chicken embryos infected with an inoculum from the mouse lungs contained not only elementary bodies but also a toxin with a titre of 320/0.5 ml. in mice which had been inoculated intravenously. Mice inoculated intranasally with yolk sac material developed pneumonitis; while those inoculated intracerebrally or intraperitoneally, although they had no signs of illness, had elementary bodies in their brains or spleens. Such brain or spleen tissue proved infective to mice when inoculated intranasally, but it was not possible to establish serial passage in mice with these suspensions by the intracerebral or intraperitoneal route. Virus was not found in lungs of mice injected intracerebrally or intraperitoneally, nor in brains or spleens of mice injected intranasally.

Three grey masked opossums (*Metachirops*) and one woolly opossum (*Caluromys laniger*) were injected intranasally with a suspension of infected mouse lung. Four or five days later the animals presented the same respiratory symptomatology as the opossum (*Metachirus nudicaudatus*) from which the agent was originally isolated. Virus was recovered from lung suspensions of all four, and pathological study demonstrated pneumonitis. The

virus was not pathogenic for guinea-pigs injected intracerebrally or intraperitoneally.

Table 1 presents a comparison of OBV and other members of the PLGV group with respect to pathogenicity for mice and guinea-pigs, and susceptibility to sulphonamides<sup>1</sup>. Investigations of possible cross-immunity were also undertaken. An immune relationship was demonstrated between OVA and OVB. Mice immunized intraperitoneally with OBV resisted intracerebral challenge with 1,000 mouse  $LD_{50}$  of OVA. In a similar test with meningopneumonitis virus (which is, like OVB, not susceptible to sulphonamides) OVB conferred no protection. It was not possible to obtain a clear-cut result on immunity by challenging mice immunized with OVB with the homologous virus intranasally. The same situation had been found with mice immunized and similarly challenged with OVA.

Neutralization tests were used to determine the relationship of OVB to mouse pneumonitis virus which behaves similarly in white mice (Table 1). The yolk sac toxin produced by the culture of OVB in the chicken embryo was neutralized by homologous immune serum from roosters injected intraperitoneally with the virus; but was not neutralized by immune serum prepared in the same manner with mouse pneumonitis virus. This lack of neutralization, together with the non-susceptibility of OVB to the sulphonamides, established a difference between OVB and mouse pneumonitis virus.

The fact that mice immunized with OVB resisted challenge with OVA raised the question that the two viruses might be identical. A difference was established, however, in that the B virus was not pathogenic for white mice injected intracerebrally, even with rich yolk sac culture.

These investigations were begun at the Carlos Finlay Institute, Bogota, Colombia, when it was jointly supported by the Ministry of Health of the Republic of Colombia and the International Health Division of the Rockefeller Foundation, and were terminated at the Research Division, American Cyanamid Company, Pearl River, New York.

### Formation and Identification of the Pigment Pterorhodin in a Mutant of *Fusarium vasinfectum* Atk.

WE are investigating the pathogenicity of *Fusarium vasinfectum* Atk. in the cotton plant *Gossypium arboreum* and the present communication deals with studies of two mutants of *F. vasinfectum* obtained by nitrous acid treatment of their conidia. The synthesis of pterorhodin pigment by a mutant of *F. vasinfectum* is also reported.

The nitrous acid treatment was carried out on normal conidia obtained from 10 day old cultures in Czapek's agar medium. A suspension containing  $5 \times 10^8$  conidia/ml. of 0.1 molar acetate buffer was prepared according to the method of Siddiqi<sup>1</sup>. A pair of nutritionally deficient mutants, one being a partial requirer of nicotinic acid and the other requiring *para* amino benzoic acid (PABA), obtained during one such treatment was further investigated. The pathogenicity of these two mutants was compared with the parent strain by different methods. It was interesting to observe that the partial nicotinic acid requirer formed a bluish violet pigment in the Czapek's agar medium supplemented with niacin. A typical pigment producing mycelia is given in Fig. 1.

It was of interest to isolate and identify the pigment, which was insoluble in common solvents like benzene, ether, chloroform, alcohol, and also in dilute acids, either in cold or on heating. It dissolved in concentrated sulphuric acid, however, to give a red solution which on dilution gave a crystalline precipitate. The pigment was slightly soluble in alkali, but it slowly became hydrolysed on keeping for some time. The absorption spectra were taken in a recording spectrophotometer and also read in a colorimeter, and the absorption maxima were found to be at 508 m $\mu$  and 535 m $\mu$ .

On an examination of the many naturally occurring pigments, we found that the *Fusarium* pigment resembled pterorhodin. A pure synthetic sample of pterorhodin was compared with the *Fusarium* pigment. The absorption spectra observed in both cases were found to be identical and the *Fusarium* pigment possessed all the chemical properties of pterorhodin<sup>2-4</sup>.

Pathogenicity tests showed that the pigment forming partial nicotinic acid requirer was found to be doubly toxic when compared with the parent strain, whereas the PABA requiring mutant was non-toxic (Fig. 2).

Fig. 1. The formation of bluish violet pigment by the partial nicotinic acid requiring mutant of *Fusarium vasinfectum*.

Fig. 2. Comparison of the toxicity of the different strains of *F. vasinfectum*. C, Control; P, PABA requiring mutant; W, wild strain; N, partial nicotinic acid requiring mutant.

The fusaric acid concentrations in the culture medium, as determined by the cup-plate method and the serial dilution method, were also more than twice that of the parent strain of *F. vasinfectum*. The pigment which required PABA formed little fusaric acid<sup>6</sup>.

We thank Dr. R. Shanmugasundaram, of the University of Sheffield, for critical discussions and help in spectrophotometric determinations, Dr. R. Purman and Professor R. Huisgen, of the University of Munich, for pterorhodin, and Professor H. Kern, of Switzerland, for fusaric acid. This work was supported in part by a grant from the U.S. Department of Agriculture.

### Esterase Zymogram Method for classifying Mycobacteria

THE biochemical tests usually used in classifying mycobacteria are based mainly on quantitative differences in enzyme activities, with the exception of the niacin test. It would be important to examine the qualitative differences in enzyme activities such as substrate specificity and multiplicity of molecular forms. Esterases are thought to be the most suitable materials for this purpose because of their wide distribution in mycobacteria and the ease with which their zymogram can be obtained by electrophoresis. Cann *et al.*<sup>1</sup> examined the esterase patterns of some groups of rapid growers and suggested that this technique could be applied to the classification of mycobacteria. The present communication describes the species (or group) specificities of esterase zymograms obtained from numbers of mycobacterial strains using an advanced technique of thin layer electrophoresis.

The mycobacterial strains used were seven strains of *M. hominis*; two of *M. bovis*; eight of *M. kansasii*; seven of *M. avium*; six of *M. fortuitum*; twelve of *M. smegmatis*; eleven of *M. phlei*; and twenty-eight non-photochromogens (of which fifteen were received from Dr. E. H. Runyon and thirteen were isolated in Japan). The strains were checked by the usual methods of classification, such as the niacin test, the nicotinamidase test, the urease test, the formamidase test, Bönicke's amidase series test, the arylsulphatase test, the heat-stable catalase, esterase<sup>2</sup> and acid phosphatase<sup>3</sup> tests, and Gordon, Smith and Mihm's *M. fortuitum* tests.

0.8–1.5 g of wet cells grown on 1 per cent Ogawa egg medium were suspended in 1–1.5 ml. of water and sonicated for 20 min with a 10 kc/s, 200 W sonic generator. The sonicate was centrifuged at 17,000 r.p.m. for 20 min and the supernatant was used as the crude enzyme preparation to be analysed.

Agar thin layer electrophoresis was carried out using the method of Ogita<sup>4</sup>. The conditions used in this experiment were as follows. The supporting gel consisted of 0.7 per cent agar and 0.8 per cent polyvinylpyrrolidone in potassium phosphate buffer, pH 6.8,  $\Delta/2 = 0.025$ . The gel plate measured 165 × 120 × 0.9 mm.  $\Delta/2$  for the buffer in the electrode vessels was 0.05. A potential of 180–200 V was applied at both ends of the agar gel layer and a current of 26–28 m.amp passed; the duration of the electrophoresis was 60–90 min. The enzyme activity was detected using a  $\beta$ -naphthylacetate-naphthanyl-diazoblu B system.

The results are summarized in Fig. 1.

Three distinct bands were observed in *M. hominis* and *M. bovis*, and the two species could not be distinguished from each other by the present esterase zymogram

Fig. 1. Esterase zymogram of mycobacteria. Intensity of reaction  $\blacksquare$  >  $\square$  >  $\square$ .  $\square$  shows the existence of some variations in position. \* Some bands were slightly shifted or missing in several strains of *M. fortuitum*.

method. In two strains of *M. hominis*, a slight shift in the position of a band was observed. *M. kansasii* gave two bands and *M. avium* two principal bands and two weaker bands. *M. fortuitum* was found to have, in general, a specific pattern consisting of five or six bands. *M. smegmatis* typically gave a pattern consisting of five bands, but some variations in one of these bands were observed in several strains. Three characteristic bands were found in *M. phlei*. *M. runyonii* seemed to show different bands from *M. fortuitum*. The patterns of non-photochromogens resembled that of *M. avium* to some extent and they could be subdivided into at least three groups according to the position of the strongest band.

In accordance with the results of Cann *et al.* in some species of rapid-growers, the esterase patterns of mycobacteria seemed to be characteristic for each species, although some variations were observed. The esterase zymogram method using the  $\beta$ -naphthylacetate-naphthanyl diazoblu B system can therefore be used as a new method of classification for mycobacteria.

### *Penicillium sclerotigenum*: a New Source of Griseofulvin

*Penicillium sclerotigenum* Yamamoto<sup>1</sup> (CMI, 68,616) has been shown to produce griseofulvin. The fungus causes tuber rots of the Chinese yam, *Dioscorea batatas*. It was grown in Roux bottles in a medium containing 75 g 'Dextrosol', 2.9 g potassium nitrate, 5.0 g potassium dihydro-orthophosphate, 1.0 g magnesium sulphate heptahydrate, 1.0 g sodium chloride, 0.5 g 'Difco' yeast extract, and 1 ml. of minor element concentrate (containing 0.1 g ferrous sulphate heptahydrate, 0.015 g copper sulphate pentahydrate, 0.05 g zinc sulphate heptahydrate, 0.01 g manganese sulphate heptahydrate and 0.01 g sodium molybdenate, in 100 ml.) made up to 1 l. with distilled water. The mycelium and broth were extracted with chloroform after 26 days growth.

A bioassay of the culture filtrate using *Botrytis allii* as the test organism showed the very characteristic effects of griseofulvin<sup>2</sup>. The presence of this antibiotic was confirmed by its isolation in low yields from both extracts as colourless needles, identity with authentic material being established by mixed melting point, and by comparison of ultra-violet and infra-red spectra and of  $R_F$  on thin layers. Isolation from mycelial extracts was hampered by the co-occurrence with griseofulvin of a colourless non-aromatic compound of closely allied polarity which was identified as ergosterol peroxide<sup>3</sup>.

We thank Prof. P. W. Brian and Dr. N. J. McCor-kindale for helpful discussion.

## PHYSIOLOGY

### Inhibition of Release of Acetylcholine by Strychnine and its Implications regarding Transmission by the Olivo-cochlear Bundle

In previous experiments, we have investigated the effects of various cholinergic blocking agents and other drugs on the release of acetylcholine (ACh) from the Ringer-Locke perfused superior cervical ganglion of the cat after injection of carbachol (0.5–1.0  $\mu$ g) into the perfusion solution or supramaximal electrical stimulation (10 c/s for 3 min) of the preganglionic trunk (ref. 1 and our work in preparation). Hexamethonium ( $10^{-4}$  molar), which does not block the release of ACh by preganglionic stimulation<sup>2,3</sup>, markedly reduced release of ACh induced by carbachol. Similarly, atropine sulphate (10–33  $\mu$ g) consistently, and  $3 \times 10^{-5}$  molar diallyl bisnortoxiferine or  $3 \times 10^{-4}$  molar dihydro- $\beta$ -erythroidine occasionally, reduced the amount of ACh released by carbachol, but not by preganglionic stimulation;  $2 \times 10^{-4}$  molar mecamylamine did not affect release of ACh with either type of stimulus. Procaine, at 50 or 10  $\mu$ g/ml., reduced release of ACh which had been induced by either preganglionic stimulation or carbachol, but at 1  $\mu$ g/ml. it was effective only against carbachol-induced release of ACh. Of all the drugs tested, only strychnine blocked or reduced selectively the release of ACh induced by preganglionic stimulation, an effect that was statistically significant ( $P < 0.05$ ) for the dosage range of 100–1.0  $\mu$ g/ml.; carbachol-induced release of ACh was reduced markedly at a concentration of 100  $\mu$ g/ml., but inconsistently or not at all at concentrations of 31.6  $\mu$ g/ml. or lower<sup>4</sup>. Strychnine in concentrations of  $10^{-6}$ – $10^{-5}$  g/ml. has been shown to reduce the output of ACh by the ileum of guinea-pig after coaxial stimulation or treatment with various drugs<sup>4</sup>. The inhibition by strychnine of the release of ACh by nerve impulse suggests a possible explanation for the apparent inconsistency between histochemical and pharmacological findings at the terminals of the olivo-cochlear bundle of Rasmussen.

The axonal terminals of the olivo-cochlear bundle, which exert a centrifugal inhibitory effect on the passage of impulses over the afferent fibres of cranial nerve VIII during auditory stimulation<sup>5</sup>, have been shown histochemically to stain distinctly for acetylcholinesterase<sup>6–8</sup>. This suggests that the olivo-cochlear bundle is cholinergic<sup>10,11</sup>. Pharmacological investigations, however, have not supported this implication. It was shown originally that strychnine, in doses as low as 0.1 mg/kg, given

intravenously, or applied topically (1/400) to the round window, or higher doses of the related drug, brucine, suppresses the neural ( $N_1$ ) inhibitory effect of stimulation of the olivo-cochlear bundle mentioned previously<sup>12</sup>. Strychnine and brucine likewise block another effect of stimulation of the olivo-cochlear bundle, the potentiation of cochlear microphonics (CM)<sup>13</sup>, which probably results from hyperpolarization of the hair cells<sup>14</sup>. Strychnine has been shown to produce blockade at peripheral sites of cholinergic transmission, but its potency in this respect is relatively low<sup>15,16</sup>. On the other hand, classical cholinergic blocking agents including D-tubocurarine, dihydro- $\beta$ -erythroidine, and atropine produce no detectable modification of either of the foregoing effects of stimulation of the olivo-cochlear bundle<sup>14,17,18</sup>. While the systemic administration of physostigmine or neostigmine<sup>19</sup> or the iontophoretic application of acetylcholine (ACh) to the vicinity of the cochlear hair cells<sup>17</sup> caused depression of the  $N_1$  response to auditory stimulation, in the latter experiments the CM response was simultaneously depressed, presumably through depolarization of the hair cells; both these actions of ACh, unlike those of stimulation of the olivo-cochlear bundle, were blocked by D-tubocurarine<sup>17,18</sup>. Thus, it seems unlikely that ACh is the neurohumoral transmitter of the olivo-cochlear bundle, despite its pharmacological actions in that vicinity and the high activity of AChE of the terminals.

ACh has been suggested to play an intermediate part in the release of the actual transmitter at the terminals of certain non-cholinergic neurones, including the neurosecretory fibres of the neurohypophysis<sup>20,21</sup>, adrenergic fibres<sup>22</sup>, and certain primary afferent fibres<sup>23</sup>. With the exception of adrenergic fibres of the cat all such fibres stain for AChE (refs. 24 and 25). This concept has been incorporated into a general hypothesis in which it was suggested that at the terminals of cholinergic fibres as well the ACh released initially by the nerve impulse may act at the same terminals to produce a brief ( $< 1.0$  msec) prolongation of depolarization and, thus, amplify the quantity of ACh released<sup>26,27</sup>. The hypothetical presynaptic cholinoreceptors involved at these various sites would not necessarily be expected to be pharmacologically identical with those at the corresponding postsynaptic sites. Thus, the action of strychnine in blocking the release of ACh from the cholinergic fibres of the superior cervical ganglion could be a result of blockade of pharmacologically distinctive presynaptic cholinoreceptive sites. Similarly, its blocking action at the terminals of the fibres of the olivo-cochlear bundle stained with AChE could be caused, at least in part, by blockade of the release by ACh of an inhibitory, or hyperpolarizing, transmitter which in turn acts at the auditory afferent terminals and hair cells. Certain features common to strychnine-sensitive inhibitory receptors and various cholinoreceptors have been pointed out<sup>28</sup>. The term "S" (strychnine-sensitive) cholinoreceptors might be assigned to the hypothetical presynaptic receptors in distinction to the well established M (muscarinic) and N (nicotinic) postsynaptic cholinoreceptors.

Our proposal does not necessarily preclude the possibility of another one<sup>14</sup>, that the prevention by strychnine of the effects of stimulation of the olivo-cochlear bundle is caused by the postsynaptic blockade of an inhibitory transmitter, as has been assumed to occur at the terminals of the Renshaw cells on the anterior horn cells<sup>29</sup>. Nevertheless, the evidence obtained at both these sites can be explained equally well in terms of a presynaptic block by strychnine of release of transmitter<sup>30</sup>. The incorporation of a step in the latter alternative mediated by ACh would then account for the presence of AChE at the terminals of the olivo-cochlear bundle. In addition, the assumption of a predominantly presynaptic site of action of strychnine would eliminate blockade by strychnine as an essential qualification for the identification of a putative inhibitory transmitter at the central nervous system<sup>31</sup>.

### Functional Behaviour of Pial and Cortical Arteries in Conditions of Increased Metabolic Demand from the Cerebral Cortex

ANY marked increase in the metabolic demands of the cerebral cortex, caused, for example, by increased activity, is accompanied by an intensification of cortical circulation<sup>1-3</sup>. This occurs independently of the systemic arterial pressure which remains unaltered. The width of the major arteries of the brain (internal carotids and vertebrals) does not change in conditions of increased cortical activity<sup>4</sup> and even diminishes after a temporary deficiency of blood supply to the brain<sup>5,6</sup>. These arteries therefore do not, in the above conditions, contribute to an increase in cerebral circulation. It was therefore necessary to learn more about the functional behaviour of both pial and cortical arteries, as the possible vascular mechanisms responsible for increase of blood supply to the cerebral cortex when its metabolic demands are heightened.

The experiments were carried out with adult rabbits, either unanaesthetized (only novocain was locally administered in the course of surgical manipulations), or under light urethane anaesthesia. The changes in diameter of pial arteries were recorded by taking serial photomicrographs of them through a trephine opening in the skull and then using an ocular micrometer to measure the diameter of various vessels on the separate frames of the films (taken successively at fixed time intervals). Investigation of cortical blood vessels was carried out on microscope slides after rapid fixation of supravital tissue. For this purpose the cerebral vessels were, whenever the experiment necessitated it, perfused with formaldehyde solution (12 per cent, with saline, both dissolved in 96°

alcohol). In unstained slides of the cortex (30 $\mu$  thick and cut along the radial arteries) all structural elements of the vascular walls could be observed because of differential refraction. The external and internal diameters were measured along the cortical arteries at intervals of 20 $\mu$ .

The local increase in cortical activity recorded (on an electroencephalogram) was induced by application of a 0.5 per cent solution of strychnine nitrate. The dilatation of pial arteries overlying the corresponding areas of the cortex is caused not by the direct effect of strychnine on vascular walls but by the influence of the cerebral cortex<sup>4</sup>. The functional behaviour of pial and cortical arteries after 1-2 min of treatment with strychnine is shown in Fig. 1. A complete stoppage of cerebral circulation for a period of 30-60 sec was produced by exsanguination from the abdominal aorta and by a subsequent pumping of blood back into the arterial system. Fig. 2 shows how pial and cortical arteries behave when the cerebral cortex is in the post-ischaemic state.

Thus the increase of metabolic demands of the cerebral cortex (caused by increased activity or a temporary stoppage of cerebral circulation) is accompanied by a dilatation of pial arteries, especially of those of smaller calibre, whereas the lumina of cortical arteries even undergo contraction. The implication is that it is the pial arteries that are to be regarded as the vascular mechanism responsible for the increase of blood supply to the cerebral cortex in the circumstances described above. Situated as they are over the surface of the brain in the porous tissue of the pia mater they are able to change their width within a very wide range. The cortical arteries, on the other hand, are in quite different conditions, for there is no free space surrounding them<sup>7,8</sup>, and their dilatation would exert pressure on the tissue elements of the cerebral cortex. Thus there is the essential significance of the fact that their external diameter does not increase even when the cerebral circulation is intensified<sup>9</sup>. The data presented here show that the internal diameter of the cortical arteries even tends to diminish. The problem of whether this contributes to increased resistance to blood flow in the cortical area concerned cannot be solved yet. The Fåhræus-Lindquist phenomenon<sup>10,11</sup>, however, may suggest that the fluidity of blood in arteries of such small calibre rises as the lumina contract. Only when this contraction of cortical arterioles (especially of very small ones) reaches a certain point (for example, in a cortical focus of convulsive activity of some 10 or 15 min duration<sup>12</sup>) can it become a cause of deficiency of blood supply<sup>3</sup>.

These results agree with previous findings<sup>13</sup>. Using an electroplethysmographic method it was shown that in man inhalation of carbon dioxide results in an increase of blood

Fig. 1. Changes in diameter (in percentage of control values) of cerebral blood vessels under conditions of increased cortical activity (in rabbits). The data represent mean ( $M$ ) and standard deviations ( $\sigma$ ).

Fig. 2. Changes in diameter (in percentage of control values) in post-ischaemic state of the cerebral cortex (in rabbits). The data represent mean ( $M$ ) and standard deviations ( $\sigma$ ).

volume only in the surface vessels of the brain; within the brain it seems to decrease.

Consequently, in conditions of increased metabolic demand from the cortex of the brain, the pattern of the functional behaviour of various parts of the cerebral arteries is not identical. Furthermore, changes in the diameters of their lumina may even proceed in opposite directions. The pial arteries seem to play the main part in the increase of the blood supply to the cerebral cortex in these conditions.

### Inhibition of Uterine Contractions *in vivo* in the Unanaesthetized Rabbit

WE have found that a non-steroidal oestrogen antagonist<sup>1</sup> will inhibit spontaneous (4  $\mu$ g/ml.) and electrically induced (20  $\mu$ g/ml.) contractions of the oestrous rat uterus *in vitro*<sup>1,2</sup>. Similar results were obtained *in vitro* with electrically stimulated uteri (about 30  $\mu$ g/ml.) removed from rabbits immediately after coitus. This report

concerns the effect of CN-55,945-27\* on uterine contractility when infused intravenously into unanaesthetized rabbits *post partum*.

Uterine contractions were recorded by means of transducer units similar to those previously described<sup>3</sup>. Such units (Fig. 1B) were calibrated (Fig. 1A) and then sutured on to the serosal surface of the myometrium overlying placental sites (Fig. 1C) in New Zealand white rabbits on the twentieth day of pregnancy. The transducer leads were run subcutaneously from a mid-ventral incision in the abdomen to an external connector which was anchored by the skin at the back of the neck (Fig. 1E). A permanent cannula was sutured into the jugular vein and exteriorized adjacent to the electrical connector (Fig. 1D). The recordings were made on an Offner (Type RS) dynograph.

Fig. 1. A, Calibration apparatus in which known weights are intermittently lowered on to one end of the transducer unit by means of a small battery operated motor; B, combination electrode-transducer unit (see ref. 3); C, transducer units on pregnant rabbit uterus (unit on right overlies placental site); D, acrylic plug holding electrical (female) connector and jugular cannula outlet; E, rabbit (Dutch-Belted strain) showing acrylic plug healed into skin of neck region.

CN-55,945-27 was dissolved in 0.6 per cent saline and infused intravenously (30 mg/kg/h). Fig. 2 is a record typical of those observed repeatedly in eleven animals on days 2-7 *post partum*. All the animals were allowed to keep and raise their young. Lines A and B (Fig. 2) show a control pattern obtained during infusion of 0.6 per cent saline. Infusion of the compound over a period of 2 h, as shown in lines C, D and E (Fig. 2), resulted in a progressive decrease in both the frequency and amplitude of uterine contractions in all the animals studied. When the infusion of CN-55,945-27 ended, uterine activity returned towards normal as shown in lines F and G (Fig. 2).

\* (1-[2-(p-[a-(p-methoxyphenyl)- $\beta$ -nitrostyryl]phenoxy)ethyl]pyrrolidine, monohydrate).

Fig. 2. Effect of intravenous infusion of CN-55,945-27 on uterine contractions *in vivo* in the unanaesthetized post partum rabbit. g, Tension in grams.

A quantitative analysis of the data presented in Fig. 2 is plotted in Fig. 3. These data were obtained by a method which we call linear displacement analysis. An inexpensive device, which is normally used to determine distances on maps, was used to trace the total record from which the recordings presented in Fig. 2 were taken. That is, the number of "miles" was traced during each interval of 15 min for the total period of infusion. Next, the horizontal length ("miles") of a 15 min period was subtracted from the total length of each of these tracings. This calculation allows the percentage decrease in uterine activity to be expressed on a 100 per cent basis. Finally, we calculated the percentage change in "linear displacement" of each interval during drug infusion from the mean of eight similar 15 min tracings during the control period. Although the meaning of this type of analysis is uncertain, we have found the method to be simple, rapid and cheap and to represent accurately the effect of various hormones and synthetic

Fig. 3. Quantitative analysis of data presented in Fig. 2 by linear displacement method (see text).

agents on uterine contractility. Previously we attempted to make use of the planimeter method<sup>4</sup> to analyse this type of data and found it very laborious. The data presented in Figs. 2 and 3 are quite typical of those obtained during forty-seven different experiments in eleven rabbits. Higher doses (for example, 60 mg/kg/h) cause a qualitatively similar but more rapid effect. The initial stimulatory effect of the compound on uterine contractions (Fig. 3) was observed in the majority of our experiments.

It should be noted that the transducer units used in this experiment are essentially uni-directional and that they were placed on the longitudinal axis of the uterus. Our results are therefore limited to the longitudinal layer of muscle and may not reflect the activity of the circular muscle. It is interesting, however, that this oestrogen antagonist can inhibit uterine motility both *in vitro* and *in vivo*. Thus, CN-55,945-27 may have clinical potential in situations in which it would be desirable to inhibit uterine activity rapidly.

We thank Mr. Ralph Hartnagel for preparing the photographs shown in Fig. 1, and Dr. Horace A. DeWald for providing the CN-55,945-27.

### Effect of Hemicholinium on the Number of Synaptic Vesicles

SYNAPTIC vesicles contain a bound fraction of acetylcholine<sup>1,2</sup>. Vesicles were identified by the quantity of acetylcholine, which was 400 molecules<sup>3</sup> or twenty to a hundred times as much<sup>4,5</sup>. Hemicholinium, on the other hand, inhibits the cellular mechanism which synthesizes acetylcholine<sup>6</sup>. Thus the question arises as to whether the number of synaptic vesicles shows any alterations after treatment with hemicholinium.

Eight albino rats (160–180 g body weight) were injected intraperitoneally with  $\alpha, \alpha$ -dimethylethanolamino-4,4'-biacetophenone (HC-3) in a dose of 10 mg/kg. Three of the animals died spontaneously 23–35 min after the injection; the rest were killed 40 min after the injection. Eight untreated rats were used as controls. The caudate nucleus and the superficial layer (stratum zonale) of the parietal cortex were subjected to routine electron microscopic investigations, using Millonig's osmic acid solution. Blocks were embedded in 'Araldite'; thin sections were prepared on an ultratome and photographed on a table electron microscope.

The numbers of synaptic vesicles were determined in a large number (more than a thousand) of axonal profiles and the surface areas of the individual profiles were estimated by means of a planimetric procedure. Axon profiles, exhibiting membrane thickenings, were designated "synaptic" profiles, whereas those without membrane

specification were regarded as "transient" profiles. The numbers of synaptic vesicles in each square micron were then calculated both for synaptic and transient axons. The results are summarized in Fig. 1.

The numbers of synaptic vesicles are higher in the axons of the parietal cortex than in the caudate nucleus. The difference is significant. Treatment with HC-3 did not induce any significant alteration in the synaptic vesicles within the caudate nucleus, whereas the decrease in the parietal cortex is highly significant. Even in the cortex, however, HC-3 did not destroy synaptic vesicles; their number decreased only to that in the caudate.

Hebb<sup>7</sup> recently reported a 90 per cent decrease of acetylcholine content in the caudate nucleus after local treatment with HC-3. A marked decrease of acetylcholine in the pons and medulla has been found after systemic administration of HC-3<sup>8</sup>, and an increased central latency (probably caused by decreased acetylcholine content) in the spike responses of Renshaw cells affected by HC-3 has been observed<sup>9</sup>.

It seems very unlikely that vesicles contained acetylcholine in their cavities when it is realized that: (a) acetylcholine is synthesized by a cytoplasmic, non-mitochondrial enzyme (choline acetylase) which may be either soluble<sup>10-12</sup> or associated with some structural components (neurotubuli or vesicles), according to species differences<sup>11,13</sup>; (b) synaptic vesicles are derived from mitochondrial membranes<sup>14</sup>; (c) treatment with HC-3 markedly reduces synthesis of acetylcholine; (d) treatment with HC-3 does not abolish the formation of synaptic vesicles; (e) acetylcholinesterase is located in surface membranes<sup>10-13</sup>. The hypothesis that acetylcholine is adsorbed and attached to the external surfaces of synaptic vesicles seems more plausible. Accordingly, the function of vesicles was only to transport acetylcholine molecules to their site of action (Fig. 2). Binding of acetylcholine to the external surface of a vesicle ( $\sim 500,000 \text{ \AA}^2$ ) could easily account for the high figures recently obtained for the quantum of acetylcholine<sup>4</sup> which are inconsistent with the extreme concentrations (up to 10 molar) required for an intravesicular localization. Also the pre-transmitter (modulator) function of acetylcholine in most of the

Fig. 2.

central synapses suggested on the basis of histochemical and electron microscopic investigations<sup>15</sup> is consistent with the location of acetylcholine at the external surfaces of synaptic vesicles.

Fig. 1.

### Effects of Vasodilators on the Isolated Taenia Coli of the Guinea-pig

DESPITE a long history of the clinical use of nitroglycerine as a powerful coronary vasodilator, very little is known about the basic mechanism by which this agent relaxes vascular smooth muscles. As a first step to search into the underlying mechanism of this relaxant action, the effect of this compound on the electrical activity of the isolated guinea-pig taenia coli was examined using the sucrose-gap technique, and this was compared with the actions of several other representative vasodilators, such as papaverine, theophylline and adenosine.

Guinea-pigs were stunned by a blow on the head, the abdomen opened and the colon was exposed. A 30 mm *in situ* length of taenia was dissected free from the underlying tissue and mounted in a sucrose-gap apparatus as described by Burnstock and Straub<sup>1</sup>, so that it lay in a horizontal insulating tube containing isotonic sucrose solution, while each end was suspended in a vertical tube through which Tyrode solution flowed. The temperature of the Tyrode solution flowing through the one vertical tube was kept below 15° C, to keep the muscle inactive, thus maintaining a stable potential against which the potential change of the preparation in the other vertical tube, kept at body temperature, could be compared.

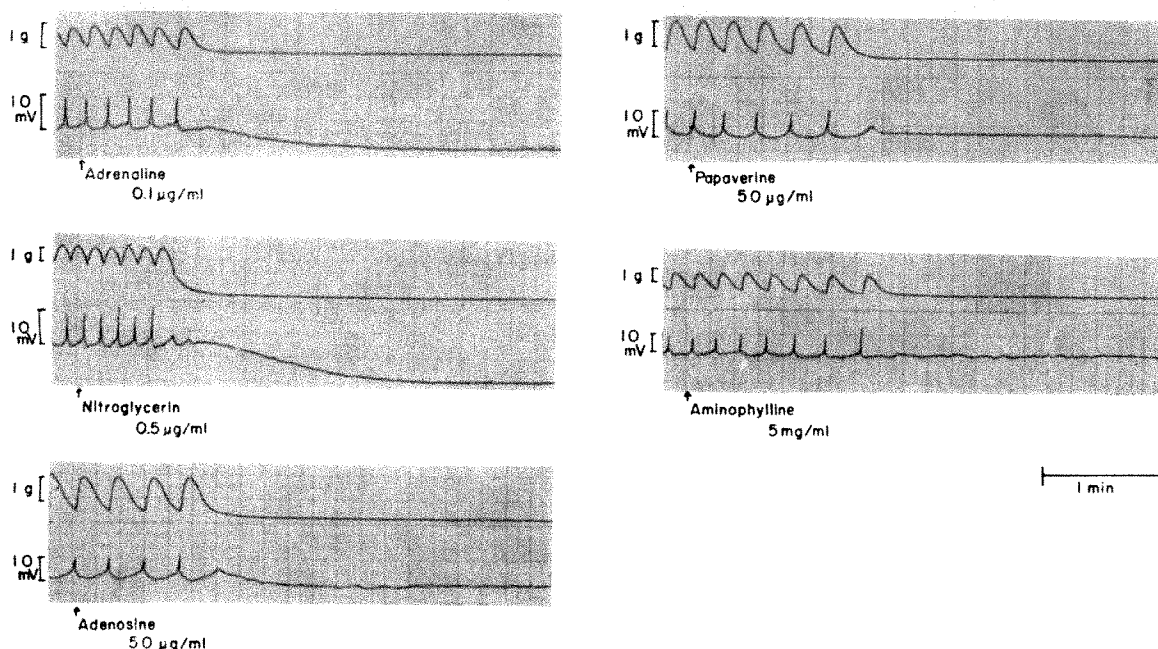

Fig. 1. Effects of vasodilators on the electrical activity of the isolated guinea-pig's taenia coli. Sucrose-gap method. Contractile tension was also recorded isometrically using a strain-gauge transducer. Although no remarkable hyperpolarization is discernible in this figure with papaverine and theophylline ethylenediamine, these compounds produced hyperpolarization in some other preparations not shown here.

Arrangements were made, using a strain-gauge transducer, to record isometric contractions of the preparation simultaneously with electrical activity. The initial tension of the muscle was adjusted to 0.5–1.0 g.

The composition of the Tyrode solution used was as follows: sodium chloride, 154; potassium chloride, 5.6; calcium chloride, 2.2; magnesium chloride, 2.1; sodium bicarbonate, 8.0; dextrose, 5.5 (mmoles). This solution was saturated with a gas mixture of 95 per cent oxygen + 5 per cent carbon dioxide.

Compounds used were: nitroglycerine, papaverine hydrochloride, theophylline ethylenediamine, adenosine and adrenaline bitartrate.

As shown in Fig. 1, all the five compounds tested induced qualitatively similar changes in the membrane potential, that is, an inhibition of spike discharge and a hyperpolarization, at the same time as they produced a relaxation of the preparation. The threshold doses for these actions were found to be  $10^{-8}$ – $10^{-9}$  for nitroglycerine,  $10^{-8}$ – $10^{-7}$  for adenosine,  $10^{-6}$  for papaverine and  $10^{-3}$  (g/ml.) for theophylline ethylenediamine. These changes are the same as those reported for adrenaline by many investigators and it seems that all these compounds could produce relaxation of this preparation through their action on the membrane activity. Further studies in our laboratory, however, revealed certain differences concerning the mechanism of the observed effects of these compounds on the membrane activity. Although the relaxant effect of papaverine and theophylline ethylenediamine persisted after complete depolarization of the membrane by isotonic potassium sulphate, the action of nitroglycerine and adenosine was abolished in the depolarized preparation, just as the effect of adrenaline was (Fig. 2). There is now considerable evidence to suggest that the tonic part of the potassium contracture in smooth muscles is maintained by the inward movement of calcium from the extracellular space into the muscle fibres. Presumably papaverine and theophylline ethylenediamine inhibited this inward movement of calcium, thereby abolishing the sustained potassium contracture. This mechanism may probably be operating, when these compounds relax the normal polarized taenia coli, in

co-operation with their stabilizing action on the membrane.

In contrast, nitroglycerine, adenosine and adrenaline, produce a change only in the polarized membrane, most probably an increase in affinity towards calcium, as is postulated by some research workers<sup>2</sup>, which results in a cessation of spike activity and a hyperpolarization, which in turn lead to a relaxation. Although it was reported earlier<sup>3</sup> that the relaxant action of adrenaline could be elicited even in the depolarized uterine muscle, the recent report by Axelsson *et al.*<sup>4</sup> demonstrated that the relaxing effect in the depolarized taenia coli could not be ascribed to adrenaline itself, but rather to some pre-

Fig. 2. Effects of vasodilators on the completely depolarized taenia coli. NG, Nitroglycerine; PV, papaverine; AS, adenosine; APH, theophylline ethylenediamine; A, adrenaline bitartrate; and A with chlorobutanol, that is, a commercial sample of adrenaline hydrochloride containing chlorobutanol as a preservative.

servatives, such as chlorobutanol, commonly contained in the commercially available adrenaline samples. Our experiments with a freshly prepared aqueous solution of adrenaline confirmed their results.

We thank Prof. T. Shigei for his encouragement.

## RADIOBIOLOGY

### Localization of Radioiodinated Endotoxin in Organs of Mice and Rabbits: Effect of Thorotrast, Trypan Blue, Endotoxin and Carbon administered intravenously

THE splenic uptake of intravenously introduced sheep erythrocyte stroma in mice is increased if certain finely divided agents (carbon, trypan blue, saccharated iron oxide, thorotrast, polystyrene latex) are injected by the same route simultaneously or before the administration of the stroma<sup>1</sup>. It seemed of interest to investigate whether the distribution of endotoxin in organs was altered in similar conditions.

Crude endotoxin ("68 per cent ethanol-precipitated aqueous ether extract"<sup>2</sup>), from *E. coli*, strain McElroy, was labelled with iodine-131 by a method similar to that of Greenwood *et al.*<sup>3</sup>; it was precipitated immediately with two volumes of chilled ethanol and the precipitate was washed with 68 per cent ethanol. The yield from 5 mg of crude endotoxin was dissolved in 10–15 ml. of saline; rabbits were given 1 ml., and mice 0.5 ml., intravenously. A sample was incubated at 37° C for 24 h and aliquots were treated with two volumes of ethanol; 86 per cent to 90 per cent of the radioactivity remained precipitable. The addition of two volumes of ethanol did not precipitate the iodine-131 which was not bound to endotoxin.

Iodine-131 was determined with Ekco equipment; whole mouse organs and aliquots of homogenized rabbit

organs were counted. To estimate iodine-131 in organs of rabbits given both thorotrast and labelled endotoxin, two counts were made with 8 days between them and the difference was multiplied by a factor of 1.99, the mean reduction in radioactivity in the organs of control rabbits given tagged endotoxin only.

The effect of trypan blue (Hopkin and Williams) and of thorotrast (Fellows 'Testagar') on the splenic and hepatic uptake of labelled endotoxin was examined in rabbits (Table 1), and the effect of thorotrast and of endotoxin was tested in mice (Table 2). Injections were given intravenously; trypan blue and thorotrast were administered 2 h, and the unlabelled endotoxin 1 day, before the labelled endotoxin. An hour after the injection of the labelled endotoxin, a rabbit given thorotrast and one of the controls died. Two hours after the injection, two rabbits appeared moribund; one of these had been given thorotrast and the other was a control. Two hours after the injection of the labelled endotoxin, the mice and the surviving rabbits were killed.

The uptake of iodine-131 in the spleens and livers of rabbits given trypan blue or thorotrast was consistently higher than in the controls, irrespective of sex and in spite of the considerable variations in body weight. The proportionate increase in uptake was greater in the spleens than in the livers. In mice given thorotrast, similar results were obtained; spleen counts in mice which had been pre-treated with endotoxin were twice as high as in the controls while the counts in the livers were only slightly larger.

In a further experiment, labelled endotoxin was injected intravenously into mice given Indian ink (0.5 ml., one in five dilution in saline of Günther Wagner 'Pelikan' ink C 11/1431a, containing approximately 10 mg carbon/dose) by the same route 2 h previously, and into controls. Groups of three treated and three untreated animals were killed 15 min, 1 h and 5.5 h after injection of the endotoxin and a group of untreated mice after 20 h; the iodine-131 was counted in the spleens, livers, neck tissues including the thyroid glands, and the hearts, lungs and kidneys (Table 3).

In the treated animals, the total iodine-131 found in the organs was larger after 15 min than in the controls; the splenic counts were undiminished at 5.5 h, although they had declined steeply in the controls. Counts in the livers, hearts, lungs and kidneys decreased in all groups; the fall was slower in the mice given carbon. In the neck tissues, counts were low early, then rose, more rapidly in the untreated than the treated mice. Certain forms of inorganic iodine are known to be taken up by the thyroid of the rat after intraperitoneal injection<sup>4</sup> and the ratios of iodide in serum: thyroid in mice and rats appear to be similar<sup>5</sup>. Rising iodine-131 counts in the neck were therefore probably a result of uptake by the thyroid gland of inorganic radioiodine released from the labelled endotoxin. In the treated mice, the delay in uptake of iodine-131 in the thyroid gland was probably caused by its slower release in the organs; thus, the metabolism of the iodinated endotoxin appeared changed.

An experiment of the same design, in which the treated mice received 0.5 ml. of endotoxin diluted one in fifty in saline 1 day before the labelled endotoxin, gave similar, but less marked, results.

The generalized Shwartzman reaction, elicited classically in rabbits by two intravenous injections of appropriate doses of endotoxin given a day apart, is characterized by

Table 1. SPLENIC AND HEPATIC UPTAKE OF LABELLED ENDOTOXIN IN RABBITS; EFFECT OF PRETREATMENT WITH TRYPAN BLUE OR THOROTRAST

Weight and sex of rabbit	Preliminary conditioning	Iodine-131 counts/sec/organ			
		Spleen		Liver	
910 g, female	Trypan blue 1 per cent 9 ml.	140		5,530	
1,470 g, female	" " " 15 ml.	98	206	4,850	5120
2,590 g, male	" " " 26 ml.	380		4,980	
1,020 g, ** female	None (control)	64		3,140	
1,580 g, female	" " "	46	61	2,640	2830
1,610 g, female	" " "	72		2,720	
2,990 g, male	Thorotrast 8.7 ml.	240		4,180	
3,340 g, * female	" 9.9 ml.	380	290	7,550	5580
4,850 g, * female	" 14.5 ml.	250		5,020	
3,510 g, * female	None (control)	26		2,020	
3,650 g, female	" " "	96	55	2,920	2450
4,029 g, male	" " "	44		2,420	

Injections were intravenous. Endotoxin was given 2 h after trypan blue or thorotrast and surviving rabbits were killed 2 h later.

Thorotrast (1 ml.) gave 375 counts/sec with the equipment set for counting iodine-131. The counts given represent iodine-131 only; for the method of estimation of the proportion of counts from the thorotrast and iodine-131, respectively, see text.

\* Died 1 h after injection of labelled endotoxin.

\*\* Moribund 2 h after injection of labelled endotoxin.

Table 2. SPLENIC AND HEPATIC UPTAKE OF LABELLED ENDOTOXIN IN MICE; EFFECT OF PRETREATMENT WITH THOROTRAST OR ENDOTOXIN

Preliminary conditioning	Interval	Between injection of conditioning agent and injection of labelled endotoxin	Between injection of labelled endotoxin and killing of mice	No. of mice in group	Mean iodine-131 counts/sec	
					Spleen	Liver
Thorotrast (0.5 ml., in 10)	2 h		2 h	5	48 (a)	880 (c)
None (controls)				5	28 (b)	470 (d)
Endotoxin (0.5 ml., in 10)	1 day		2 h	9	37 (e)	238 (g)
None (controls)				9	17 (f)	202 (h)

All injections were intravenous. Significance of differences between means: (a) vs (b):  $0.01 < P < 0.02$ ; (c) vs (d), (e) vs (f) and (g) vs (h):  $P < 0.01$ .

Table 3. FATE OF LABELLED ENDOTOXIN IN MICE AFTER INTRAVENOUS INJECTION: EFFECT OF PRETREATMENT WITH INDIAN INK

Preliminary conditioning	Interval between endotoxin administration and killing of animals	Spleen	Mean iodine-131 counts/sec (three mice)					Iodine-131 accounted for (per cent of that injected)	
			Liver	Heart, lungs, kidneys	Neck tissues, including thyroid gland				
Indian ink		720	7,490	1,180	58				
None (controls)	15 min	380	5,920	690	37	66			50

Indian ink		82	1,000	360	1,480				20
None (controls)	20 h	22	530	170	4,940				40

Indian ink 0.5 ml, diluted 1 in 5 in saline (10 mg of carbon/dose) was injected intravenously. Labelled endotoxin was injected 2 h later into all animals.

capillary thrombi, those in the renal glomeruli leading to cortical necrosis<sup>6</sup>. Thorotrast, trypan blue<sup>7</sup>, Indian ink and saccharated iron oxide<sup>8</sup> have been used successfully in place of the first dose of endotoxin; it has been suggested that these substances block the reticulo-endothelial system, and thus prevent the removal of the endotoxin from the circulation<sup>8</sup>. In pregnant rats, however, the activity of the reticulo-endothelial system was found to be increased, yet susceptibility to the deposition of thrombi in the renal glomerular capillaries was greater<sup>9</sup>; in mice which were given thorotrast intravenously, labelled endotoxin injected by the same route after certain intervals of time was deposited in the liver in quantities greater than in the controls<sup>10</sup>. Endotoxin was injected intravenously into rabbits and 1 day later endotoxin labelled with chromium-51 was injected into these animals and into untreated controls<sup>11</sup>. In the treated rabbits, the splenic uptake of chromium-51 was larger and the hepatic uptake was somewhat smaller.

The experiments reported here suggest that the more severe effects of endotoxin in rabbits previously treated with agents such as carbon, thorotrast and trypan blue<sup>8</sup> were caused not by reduced uptake of endotoxin by reticulo-endothelial organs but, rather, by increased uptake and delay in the disposal of the endotoxin lodged in the liver and spleen; this delay could itself have contributed to the presence of larger amounts of endotoxin in the spleens and livers of treated animals. The findings may be relevant to the mechanism of the generalized Schwartzman reaction, since the preliminary injection of endotoxin also led to increased uptake in the spleen and liver of a further dose of endotoxin given on the following day, and to delay in the clearance of endotoxin injected in the second dose.

## CYTOLOGY

### Internal Asynchrony in Late Replicating X Chromosomes

DURING investigation of patients with Klinefelter's syndrome, autoradiography of chromosome preparations was carried out in a number of cases. The main object of this

investigation was to determine the number and nature of late replicating chromosomes, and the results agree with the assumption that one middle group chromosome replicates late in the S phase in individuals with forty-seven (XXY) and forty-six (XX) chromosomes, two in those with forty-eight (XXXY) chromosomes and three in those with forty-nine (XXXXY) chromosomes. In addition, it was found that in many instances the late replicating chromosomes had a peculiar internal labelling pattern.

Internal asynchrony has been recorded in late replicating X chromosomes<sup>1</sup>, but the consistent pattern described later was not seen<sup>1</sup>. In lightly labelled cells the centromeric region was found to be relatively free of label<sup>2</sup>.

Three types of chromosomes could be distinguished during the present investigation. One was labelled uniformly on the whole length of the chromosome. Another showed a distinct "gap" in the labelling over the centromeric region (Fig. 1). Finally, some chromosomes showed an intermediary pattern.

The chromosome investigations were carried out in most instances on blood cells<sup>3</sup>, in one case on fibroblasts<sup>4</sup>. Tritiated thymidine was added to the suspension 5-6 h before collection of the cells giving a final concentration of 1 µc./ml. 'Colcemid' was added 3 h later. The slides were covered with liquid emulsion (Ilford K 5). Cells which were well spread and showed an intermediate amount of labelling were photographed. The silver grains were then removed<sup>5</sup>, the cells were restained with Giemsa, and compared with the photographic pictures. A total of fourteen individuals was investigated. The results are listed in Table 1.

Table 1

Diagnosis	Karyotype	No. of patients	No. of X chromosomes investigated	No. of these showing definite "gap"
Klinefelter's syndrome skin cultures	47 (XXY)	1	14	3 (21.4 per cent)
Klinefelter's syndrome blood cultures	47 (XXY)	7	105	51 (48.6 per cent)
" "	48 (XXXXY)	1	56	32 (57.1 per cent)
" "	49 (XXXXXY)	1	69	31 (44.9 per cent)
" "	46 (XX)	1	22	12 (54.5 per cent)
Normal females blood cultures	46 (XX)	3	54	30 (55.6 per cent)
Total		14	320	159 (49.7 per cent)

Approximately half of the observed X chromosomes showed a definite "gap" in the labelling over the centromeric region. Only three presumed X chromosomes showed a similar gap outside this region, in all instances on the long arms. No connexion with secondary constrictions could be demonstrated. These only occurred in 4 per cent of the late replicating X chromosomes. A less distinct labelling pattern was seen in 18 per cent of the late replicating X chromosomes. The rest was diffusely labelled on the entire length of the chromosome. The skin cells showed rather few (3/14) characteristically labelled chromosomes. This may be the result of a different rate of synthesis in the fibroblast cultures. The behaviour of the late replicating X chromosomes in the poly-X Klinefelter's is of special interest. In the subjects with forty-eight (XXXY) chromosomes, twenty-six cells were investigated. In seven of these both labelled X chromosomes showed a definite gap, in nine only one chromosome, and in ten none. In the patient with forty-

Fig. 1. Eight late replicating X chromosomes showing a gap in the pattern of labelling. The chromosomes are shown covered with silver grains, and after these have been removed and the chromosomes re-stained. ( $\times$  c. 1,000.)

nine (XXXXY) chromosomes, twenty-three cells were distributed as follows. Four cells showed the pattern in three chromosomes, five in two, nine in one, and five showed no chromosomes with a distinct "gap" in the centromeric region.

The distribution between the cells showing two, one or none in patients with forty-eight (XXXY) chromosomes and three, two, one or none in those with forty-nine (XXXXY) chromosomes is not significantly different from the distribution that would be expected if the labelling pattern occurred at random with a frequency of 0.5. The X chromosomes in these cases may not be exactly parallel in their time sequence of replication.

The significance of the internal asynchrony of the X chromosome is not clear. Only future research will show whether the phenomenon has anything to do with the assumption that not all parts of the late replicating X chromosome are genetically inactive, for example, the  $Xg^+$  locus<sup>6</sup>.

## BIOCHEMISTRY

### Lactate Dehydrogenase Isoenzymes in Chicken Tissues

LACTATE dehydrogenase isoenzymes from a variety of animal sources have been reported to differ in a number of their properties, including substrate affinities<sup>1,2</sup>, utilization of coenzyme analogues<sup>3</sup>, substrate specificity<sup>4</sup>, thermal stability<sup>5</sup> and sensitivity to inhibitors<sup>6,7</sup>. A regular gradation in these properties has been found which appears to correlate with the difference in electrophoretic mobility of each isoenzyme fraction. This difference is thought<sup>8,9</sup> to be determined by their A and B sub-unit composition. According to these workers,  $LD_1$  and  $LD_5$  are "pure types" comprising four B and four A sub-units, respectively, and  $LD_{2-4}$  are intermediate hybrid types. Cahn *et al.*<sup>9</sup> report the presence of five lactate dehydrogenase isoenzymes in young chicken tissues, the heart muscle isoenzyme being a tetramer of four B sub-units and the breast muscle isoenzyme a tetramer of four A sub-units. We could not confirm the existence of five bands of activity in adult tissues, and this communication reports studies on isoenzymes derived from adult chicken tissues which showed different properties but similar electrophoretic mobility.

Adult chickens were killed by breaking their necks, the tissues excised within 10–15 min and stored at  $-18^\circ\text{C}$  until required, except for two birds, the tissues of which were used immediately. Extracts were prepared in ice cold 0.067 molar Sørensen phosphate buffer, pH 7.4, using a Potter–Elvehjem homogenizer. After centrifuging at 6,000g for 20 min at  $4^\circ\text{C}$ , the supernatants were removed for enzyme analysis. Cellulose acetate electrophoresis was carried out according to Kohn<sup>10</sup> and the isoenzymes located by a tetrazolium staining technique<sup>11</sup>. For isoenzyme studies, the strips were cut into 3 mm sections and eluted with phosphate buffer. Polyacrylamide gel electrophoresis was carried out in a vertical apparatus<sup>12</sup> at pH 9.2. Starch-block electrophoresis in barbitone buffer (I 0.1; pH 8.6) was used as a quantitative procedure, the isoenzymes being eluted from 1 cm strips as described by Plummer *et al.*<sup>13</sup>. Dehydrogenase activities were determined spectrophotometrically at pH 7.4 using final concentrations of 0.7 mmolar pyruvate<sup>14</sup> or 3.3 mmolar 2-oxobutyrate<sup>4</sup> and 0.35  $\mu\text{moles}$   $\text{NADH}_2$ . In the inhibition experiments, potassium oxalate or urea to give final concentrations of 0.2 mmolar and 2 molar, respectively, were incorporated into the reaction mixture (3.0 ml.). Enzyme-inhibitor mixtures were allowed to stand for 30 min at  $25^\circ\text{C}$  before determining the activity at 340 m $\mu$  in a spectrophotometer.

The isoenzyme patterns of chicken heart and breast muscle are shown in Fig. 1 together with that of a human haemolysate obtained by starch-block electrophoresis. The single band from each of the chicken tissues had the same mobility and coincided with that of human  $LD_4$ , but the activity of the heart isoenzyme with 2-oxobutyrate as substrate was much greater than that of the breast isoenzyme. Electrophoresis on cellulose acetate at pH 8.6 and on polyacrylamide gel at pH 9.2 of extracts of all the principal chicken organs from five different birds showed one chief band of activity with a mobility very similar to that of human  $LD_4$ . In one hen and one cock bird, in the kidney and liver extracts only, traces of two other isoenzyme bands, with approximately the mobility of human  $LD_1$  and  $LD_2$  were detected.

Michaelis constants for pyruvate and 2-oxobutyrate of the partially purified heart and breast isoenzyme fractions were determined using Lineweaver–Burk plots, and the results, together with those for the crude tissue extracts and those for human  $LD_1$  and  $LD_5$ , are shown in Table 1. The heart isoenzyme has an affinity for pyruvate four and a half times greater than that of the breast isoenzyme, and an affinity for 2-oxobutyrate seven times greater.

Fig. 1. Lactate dehydrogenase isoenzymes of chicken heart (A), chicken breast (B), and human haemolysate (C), obtained by starch-block electrophoresis in barbitone buffer, pH 8.6. Substrates: 0.7 mmolar pyruvate (—) and 3.3 mmolar 2-oxobutyrate (///).

The  $K_m$  values of the heart isoenzyme are very similar to those of  $LD_1$ , while the values for breast for both substrates are slightly lower than for  $LD_5$ . The other tissues had intermediate values, which were, however, closer to those for heart. This difference in substrate affinities is also reflected in the different ratios of activity with 2-oxobutyrate to those with pyruvate. Heart isoenzyme had the highest activity ratio and breast the lowest with the other lying between the two.

Oxalate has been shown to inhibit selectively human  $LD_1$  while having little effect on  $LD_5$  (ref. 15), and was found to differentiate similarly between chicken heart and breast isoenzymes (Table 1) although the chicken tissues were less affected than the human. In the same way 2 molar urea, which preferentially inhibits  $LD_5$  (ref. 16), inhibited the chicken breast isoenzyme much more than the heart isoenzyme (Table 1), although both were less sensitive to urea than human  $LD_1$  and  $LD_5$ .

Table 1. SOME PROPERTIES OF CHICKEN AND HUMAN TISSUE LACTATE DEHYDROGENASE ISOENZYMES

Source of tissue	$K_m$ (mmoles)	Ratio of dehydrogenase activities: 2-oxo-butyrate/pyruvate	% Inhibition produced by 0.2 mmolar oxalate (pyruvate)	% Inhibition produced by 2 molar urea (2-oxo-butyrate)
Chicken:				
heart	0.095	0.98	0.85	71
kidney	0.110	1.28	0.73	67
ova	0.110	1.45	0.78	63
red cells	0.120	1.43	0.80	58
liver	0.130	1.28	0.71	61
spleen	0.097	1.33	0.73	59
testis	0.150	1.50	0.77	63
leg muscle	0.200	1.26	0.61	45
breast muscle	0.340	6.30	0.37	24
Chicken:				
heart isoenzyme	0.084	0.90	0.89	67
breast isoenzyme	0.390	6.40	0.40	25
Human:				
$LD_1$	0.080	0.84	0.95	70
$LD_5$	0.830	10.00	0.31	32

All results are the mean of duplicate determinations on three birds. Human  $LD_1$  was obtained from heart muscle, and  $LD_5$  from skeletal muscle.

This finding of one band of activity with the same mobility in different tissues is anomalous. It suggests either that the difference in electrophoretic mobility is so small as to be undetectable by what are usually very effective techniques, or that the intermediate hybrid isoenzymes are very unstable, or that they are present in the young bird and disappear in the adult.

These results do, however, support the idea that chicken heart and breast muscle isoenzymes constitute extreme types of lactate dehydrogenase and that although they have the same or nearly identical electrophoretic mobility, they have different properties strongly suggestive of different sub-unit composition resembling B and A sub-units, respectively.

I thank Dr. B. J. Houghton for his advice and support during this work and St. Mary's Hospital Endowment Fund for a research grant.

### Uptake of 5-Iodo-deoxyuridine by a Single Colony of Developing Embryos of *Arbacia punctulata*

PREVIOUS investigations have shown that 5-iodo-deoxyuridine (IUDR), an analogue of thymidine, is incorporated into DNA and within certain limitations can be used as an indicator of DNA synthesis (refs. 1-4, and work of Kreuger and others in preparation). Details of incorporation and elimination of iodo-deoxyuridine in various cells of mice may be found in a review<sup>4</sup>. According to the authors IUDR is a "convenient, sensitive, and specific tracer of DNA metabolism *in vivo*". Incorporation of IUDR labelled with iodine-131 has been used as an indication of the rate of DNA synthesis at different stages of the developing sea urchin embryo<sup>5</sup>. The facility of detecting the  $\gamma$ -radiation of iodine-131 made it seem possible to use iodine-131 labelled IUDR to follow DNA synthesis in the same group of living cells without fixation, extraction, or digestion of the cells. This communication pursues the use of repetitive exposure to labelled IUDR of a single colony of sea urchin embryos as a method for the investigation of developmental changes in the rate of DNA synthesis in the living cell.

Eggs and embryos of the sea urchin, *Arbacia punctulata*, were used. Each experiment was confined to the eggs obtained from a single female. The eggs were collected, washed, fertilized, and suspended in 500 ml. of sea water at the prevailing temperature of sea water (19° C–20° C)<sup>5</sup>. After fertilization, 20 ml. of the embryo suspension was taken to be used as the continuous culture (that single colony of embryos which was to be exposed to

repeated "pulses" of labelled IUDR). After incubation in labelled IUDR (121  $\mu\text{Ci/l.}$ ) for 30 min, the colony of embryos was washed four times in sea water, counted in a well-type  $\gamma$ -ray spectrometer, and maintained in 20 ml. of sea water until the next pulse. From the original embryo suspension, periodic 20 ml. aliquots were removed, incubated in labelled IUDR for 30 min, washed four times in sea water, and counted. The labelled IUDR was prepared and diluted as described previously<sup>5</sup>. Concentrations of labelled IUDR are given in Table 1.

Table 1. UPTAKE OF LABELLED IUDR BY EMBRYOS

Time after fertilization (h)	Individual groups of embryos		Single colony of embryos	
	Aliquots (c.p.m.)	Aliquots summed (c.p.m.)	Cumulative pulses (c.p.m.)	Uptake/pulse (c.p.m.)
3.5	5,590	5,590	5,216	5,216
4.5	4,526	10,116	10,821	5,105
5.5	5,910	16,026	16,083	5,762
9.0	9,842	25,868	22,941	6,858
12.0	8,059	33,927	29,849	6,908
14.0	7,975	41,902	32,246	2,397

In experiments in which a single colony of embryos was repeatedly incubated with labelled IUDR at progressive stages of development (those exposed to pulses of the radioactive compound) the embryos took up increasing amounts of labelled IUDR with each pulse. Table 1 presents the amount of radioactivity remaining in the embryos after each pulse, after they have been washed in sea water to remove all activity that can diffuse from the embryos. Thus, the c.p.m. represent the sum of two fractions of radioactivity, the acid-soluble fraction, which contains the precursor pool of intermediary DNA metabolites (which apparently is very small), and the acid-insoluble fraction containing DNA<sup>5</sup>. The last column in Table 1 shows the amount of uptake consequent to each pulse of labelled IUDR.

Simultaneously with the administration of each pulse to the continuous colony, an aliquot of embryos from the original suspension was taken and treated similarly. These control experiments were carried out to test the possible effects of repeated administration of labelled IUDR and repeated washing. In Table 1, the amount of uptake at each developmental stage is shown and the sums of these individual measurements are compared with the values obtained in the pulse experiment.

Preliminary investigation of the stability of labelled IUDR in sea water indicates that the molecule undergoes changes when it remains in solution for as long as 24 h (20° C). Very little labelled IUDR is incorporated by the embryos from such solution. This effect on labelled IUDR could be caused by bacterial action.

In these experiments involving the use of consecutive pulses of labelled IUDR with a single colony of developing embryos, it is anticipated that the amount of uptake of labelled IUDR will be cumulative and be related to the rate of DNA synthesis of the embryos. Table 1 shows such a cumulative response. Embryo aliquots incubated simultaneously with the administration of each pulse quantitatively demonstrate the amount of uptake which occurs at a given time after fertilization. The sum of these individual aliquots is approximately equivalent to the cumulative amounts in the single colony. By 9 h, however, the single colony shows decreased uptake as compared with the individual aliquots. This may be an effect of the accumulation of labelled IUDR in the embryos of the single colony. It may also be caused by experimental error or loss of cells as a result of repeated washing.

The primary pathway of degradation of IUDR in mammalian systems is by way of iodouracil which is then de-iodinated<sup>6</sup>. Degradation of IUDR in sea water or in the sea urchin embryo has not been investigated. It was, however, observed that solutions of labelled IUDR, if not used within a week of synthesis, were markedly less effective in experiments with the embryos. Preliminary work shows that the stability of labelled IUDR changes if it is allowed to remain diluted with sea water for as long as

24 h. This, however, is not considered to be significant in investigations concerned with developmental stages to gastrulation (15–19 h after fertilization) if fresh solutions of labelled IUDR are made shortly before fertilization.

In a previous publication<sup>5</sup>, it was shown that the rate of incorporation of IUDR by sea urchin embryos increases up to about 16 h after fertilization. At this time it was found that the rate of incorporation begins to decrease and ultimately reaches a very low level. It may be that this decrease of the rate of incorporation, which was most evident during the second day of development, was caused in part by a change in the IUDR molecule, as a result of bacterial action.

The present experiments show that successive changes in the rate of uptake of labelled IUDR can be detected at different stages of development in the same group of living embryos. It is anticipated that these changes reflect primarily changes in the rate of DNA synthesis. Other factors, however, such as developmental changes in the facility with which the IUDR moves across the cell membrane, may be reflected in the results.

### Hyperglycaemia induced by Insulin B Chain in Dietary Diabetes in Rats

WE have recently shown that the intraperitoneal injection of reduced insulin B chain complexed with an equal amount of crystalline bovine serum albumin produces a significant hyperglycaemia in normal rats<sup>1</sup>. In accordance with the theory proposed by Ensink, Mahler and Vallance-Owen<sup>2</sup> we assume that this effect is due to the inhibition of endogenous insulin activity by the complex of reduced insulin B chain and albumin.

The possibility of demonstrating the effect of the B chain in normal animals seems to make it more likely that this mechanism operates in diabetes, as, if increased insulin splitting is a factor in diabetes, there would be relatively less intact insulin and more B chain present. The obvious next step in the investigation of this phenomenon was to investigate the action of B chain in animals in a diabetes-like state. Alloxanized or depancreatized animals present well known variability and maintenance problems, and it was decided initially to try animals on a high fat, high protein diet. Such diets produce a condition analogous to "starvation diabetes", which has been quite thoroughly

Table 1. EFFECT OF REDUCED INSULIN B CHAIN-ALBUMIN COMPLEX ON THE BLOOD GLUCOSE OF RATS ON NORMAL AND DIABETOGENIC DIETS

No. of rats	Diet	Injection*	Blood glucose, mg/100 ml., mean $\pm$ standard error			
			Control	30 min	60 min	90 min
17	Normal	1 mg albumin	71 $\pm$ 1.8	75 $\pm$ 1.8	76 $\pm$ 1.1	80 $\pm$ 1.8
20	Normal	1 mg B chain + 1 mg albumin	68 $\pm$ 1.5	83 $\pm$ 2.0	89 $\pm$ 2.0	82 $\pm$ 1.7
		Significance, <i>P</i> value	> 0.2	< 0.02	< 0.001	> 0.4
8	Diabetogenic	1 mg albumin	80 $\pm$ 1.4	89 $\pm$ 3.0	85 $\pm$ 2.8	90 $\pm$ 4.1
9	Diabetogenic	1 mg B chain + 1 mg albumin	76 $\pm$ 1.5	113 $\pm$ 3.7	131 $\pm$ 4.3	108 $\pm$ 4.8
		Significance, <i>P</i> value	< 0.1	< 0.001	< 0.001	0.02

\* All injections were in 1 ml. of 0.0062 molar cysteine - 0.02 molar *tris* buffer and two of each were given, one at time zero and one at 31 min.
